

Intro to R

Data Cleaning

Recap on summarization

- `summary(x)`: quantile information
- `summarize`: creates a summary table of columns of interest
 - combine with `across()` to programmatically select columns
- `count(variable)`: how many of each unique value do you have
- `group_by()`: changes all subsequent functions
 - combine with `summarize()` to get statistics per group
- `plot()` and `hist()` are great for a **quick snapshot** of the data

[Cheatsheet](#)

Recap on data classes

- tibbles show column classes!
- `as.CLASS_NAME(x)` can be used to change the class of an object `x`
- Logic class objects only have `TRUE` or `False` (without quotes)
- The repeat `rep()` and `seq()` functions help you create vectors with `to` and `from` arguments (and others)
- `sample()` makes random vectors. Can be used for integers or double depending on what it is sampling from.
- matrix has columns and rows but is all one data class
- lists can contain multiples of any other class of data including lists!
- The `lubridate` package is helpful for dates and times

[Cheatsheet](#)

Data Cleaning

In general, data cleaning is a process of investigating your data for inaccuracies, or recoding it in a way that makes it more manageable.

MOST IMPORTANT RULE - LOOK AT YOUR DATA!

Dealing with Missing Data

Missing data types

One of the most important aspects of data cleaning is missing values.

Types of “missing” data:

- **NA** - general missing data
- **NaN** - stands for “**N**ot **a** **N**umber”, happens when you do $0/0$.
- **Inf** and **-Inf** - Infinity, happens when you divide a positive number (or negative number) by 0.

Finding Missing data

- `is.na` - looks for NAN and NA
- `is.nan` - looks for NAN
- `is.infinite` - looks for Inf or -Inf

```
test<-c(0, NA, -1)  
test/0
```

```
[1] NaN  NA -Inf
```

```
test <- test/0  
is.na(test)
```

```
[1] TRUE  TRUE FALSE
```

```
is.nan(test)
```

```
[1] TRUE FALSE FALSE
```

```
is.infinite(test)
```

```
[1] FALSE FALSE  TRUE
```

Useful checking functions

- any will be TRUE if ANY are true
 - `any(is.na(x))` - do we have any NA's in x?

```
A = c(1, 2, 4, NA)
B = c(1, 2, 3, 4)
any(is.na(A)) # are there any NAs - YES/TRUE
```

```
[1] TRUE
```

```
any(is.na(B)) # are there any NAs - NO/FALSE
```

```
[1] FALSE
```

Finding **NA** values with **count()**

Check the values for your variables, are they what you expect?

`count()` is a great option because it gives you:

1. The unique values
2. The amount of these values

Check if rare values make sense.

```
library(jhur)
bike <- read_bike()

bike %>% count(subType)
```

```
# A tibble: 4 × 2
  subType      n
  <chr>    <int>
1 STCLN         1
2 STRALY        3
3 STRPRD     1623
4 <NA>          4
```

naniar

Sometimes you need to look at lots of data though... the [naniar package](#) is a good option.

The `pct_complete()` function shows the percentage that is complete for a given data object.

```
#install.packages("naniar")  
library(naniar)  
x = c(0, NA, 2, 3, 4, -0.5, 0.2)  
pct_complete(x)
```

```
[1] 85.71429
```

```
test
```

```
[1] NaN    NA -Inf
```

```
pct_complete(test) # doesn't count infinite values as missing
```

```
[1] 33.33333
```

Air quality data

The `airquality` dataset comes with R about air quality in New York in 1973.

```
?airquality # use this to find out more about the data
airqual <- tibble(airquality)
airqual
```

```
# A tibble: 153 × 6
   Ozone Solar.R Wind Temp Month Day
  <int>   <int> <dbl> <int> <int> <int>
1     41    190   7.4    67     5     1
2     36    118    8     72     5     2
3     12    149  12.6    74     5     3
4     18    313  11.5    62     5     4
5     NA     NA  14.3    56     5     5
6     28     NA  14.9    66     5     6
7     23    299   8.6    65     5     7
8     19     99  13.8    59     5     8
9      8     19  20.1    61     5     9
10    NA    194   8.6    69     5    10
# ... with 143 more rows
```

naniar: pct_complete()

```
pct_complete(airquality)
```

```
[1] 95.20697
```

naniar plots

The `gg_miss_var()` function creates a nice plot about the number of missing values for each variable.

```
gg_miss_var(airqual)
```

Missing Data Issues

Recall that mathematical operations with **NA** often result in **NAs**.

```
sum(c(1, 2, 3, NA))
```

```
[1] NA
```

```
mean(c(2, 4, NA))
```

```
[1] NA
```

```
median(c(1, 2, 3, NA))
```

```
[1] NA
```

Missing Data Issues

This is also true for logical data. Recall that **TRUE** is evaluated as 1 and **FALSE** is evaluated as 0.

```
x = c(TRUE, TRUE, TRUE, TRUE, FALSE, NA)  
sum(x)
```

```
[1] NA
```

```
sum(x, na.rm = TRUE)
```

```
[1] 4
```

`filter()` and missing data

Be careful with missing data using subsetting:

`filter()` removes missing values by default. Because R can't tell for sure if an NA value meets the condition. To keep them need to add `is.na()` conditional.

filter() and missing data

```
df
```

```
# A tibble: 6 × 2
```

	Dog	Cat
	<dbl>	<dbl>
1	0	NA
2	NA	8
3	2	6
4	3	NA
5	1	2
6	1	NA

```
df %>% filter(Dog < 3)
```

```
# A tibble: 4 × 2
```

	Dog	Cat
	<dbl>	<dbl>
1	0	NA
2	2	6
3	1	2
4	1	NA

filter() and missing data

```
df %>% filter(Dog < 3 | is.na(Dog))
```

```
# A tibble: 5 × 2
```

	Dog <dbl>	Cat <dbl>
1	0	NA
2	NA	8
3	2	6
4	1	2
5	1	NA

To remove rows with **NA** values for a variable use **drop_na()**

A function from the `tidyr` package.

```
df %>% drop_na(Dog)
```

```
# A tibble: 5 × 2
```

	Dog <dbl>	Cat <dbl>
1	0	NA
2	2	6
3	3	NA
4	1	2
5	1	NA

To remove rows with **NA** values for a data frame use **drop_na()**

This function of the `tidyr` package drops rows with **any** missing data in **any** column when used on a df.

```
df %>% drop_na()
```

```
# A tibble: 2 × 2
  Dog   Cat
<dbl> <dbl>
1     2     6
2     1     2
```

Drop columns with any missing values

Use the `miss_var_which()` function from `naniar`

```
df<-df %>% mutate(test =c(1,2,3,4,5,6))
df
```

```
# A tibble: 6 × 3
  Dog   Cat test
<dbl> <dbl> <dbl>
1     0    NA    1
2    NA     8    2
3     2     6    3
4     3    NA    4
5     1     2    5
6     1    NA    6
```

```
miss_var_which(df) # which columns have missing values
```

```
[1] "Dog" "Cat"
```

Drop columns with any missing values

```
df %>% select(!miss_var_which(df))
```

```
# A tibble: 6 × 1
```

```
  test
```

```
<dbl>
```

```
1     1
```

```
2     2
```

```
3     3
```

```
4     4
```

```
5     5
```

```
6     6
```

Removing columns with threshold of percent missing row values

```
is.na(df) %>% head(n = 3)
```

```
      Dog   Cat test  
[1,] FALSE  TRUE FALSE  
[2,]  TRUE FALSE FALSE  
[3,] FALSE FALSE FALSE
```

```
colMeans(is.na(df))#TRUE and FALSE treated like 0 and 1
```

```
      Dog      Cat      test  
0.1666667 0.5000000 0.0000000
```

```
df %>% select(which(colMeans(is.na(df)) < 0.2))# remove if over 20% missing
```

```
# A tibble: 6 × 2
```

```
      Dog test  
  <dbl> <dbl>  
1      0     1  
2     NA     2  
3      2     3  
4      3     4  
5      1     5  
6      1     6
```

Change a value to be NA

The `na_if()` function of `dplyr` can be helpful for this. Let's say we think that all 0 values should be NA.

```
df %>% head(n = 3)
```

```
# A tibble: 3 × 3
  Dog   Cat test
<dbl> <dbl> <dbl>
1     0   NA     1
2    NA     8     2
3     2     6     3
```

```
df %>% mutate(Dog = na_if(Dog, 0))
```

```
# A tibble: 6 × 3
  Dog   Cat test
<dbl> <dbl> <dbl>
1    NA   NA     1
2    NA     8     2
3     2     6     3
4     3   NA     4
5     1     2     5
6     1   NA     6
```

Think about NA

Sometimes removing NA values leads to distorted math - be careful! Think about what your NA means for your data (are you sure ?).

Is an NA for values so low they could not be reported? Or is it this and also if there was a different issue?

Think about **NA**

If it is something more like a zero then you might want it included in your data like a zero.

Example: - survey reports **NA** if student has never tried cigarettes - survey reports 0 if student has tried cigarettes but did not smoke that week

You might want to keep the **NA** values so that you know the original sample size.

Word of caution

Calculating percentages will give you a different result depending on your choice to include NA values.

```
red_blue
```

```
# A tibble: 3 × 2
  color col_count
  <chr>     <int>
1 blue         3
2 red          3
3 <NA>         3
```

```
red_blue %>% mutate(percent =
  col_count/sum(pull(red_blue, col_count)))
```

```
# A tibble: 3 × 3
  color col_count percent
  <chr>     <int>   <dbl>
1 blue         3    0.333
2 red          3    0.333
3 <NA>         3    0.333
```

Word of caution

```
red_blue %>% mutate(percent =  
  col_count/sum(pull(drop_na(red_blue), col_count)))
```

```
# A tibble: 3 × 3  
  color col_count percent  
  <chr>    <int>    <dbl>  
1 blue         3      0.5  
2 red          3      0.5  
3 <NA>         3      0.5
```

Should you be dividing by 9 or 6?

It depends on your data and what **NA** might mean.

Pay attention to your data and your **NA** values!

Summary

- `is.na()`, `any(is.na())`, `count()`, and functions from `naniar` like `gg_miss_var()` can help determine if we have NA values
- `filter()` automatically removes NA values - can't confirm or deny if condition is met (need `| is.na()` to keep them)
- `drop_na()` can help you remove NA values from a variable or an entire data frame
- NA values can change your calculation results
- think about what NA values represent

Recoding Variables

Example of Recoding

Say we have some data about samples in a diet study:

```
data_diet
```

```
# A tibble: 12 × 4
  Diet Gender Weight_start Weight_change
<chr> <chr>      <int>      <int>
1 A     Male      225         3
2 B     m        105        -3
3 B     Other     229        18
4 A     F         110         6
5 B     Female     159         2
6 B     M         199        14
7 A     f         120         5
8 B     O         201        -9
9 B     Man       233        -5
10 A    f         108         0
11 B    F         118        12
12 B    O         121         8
```

Oh dear...

This needs lots of recoding.

```
data_diet %>%  
  count(Gender)
```

```
# A tibble: 9 × 2  
  Gender      n  
  <chr>   <int>  
1 f         2  
2 F         2  
3 Female    1  
4 m         1  
5 M         1  
6 Male      1  
7 Man       1  
8 O         2  
9 Other     1
```

dp1yr can help!

Using Excel to find all of the different ways gender has been coded, could be hectic!

In dp1yr you can use the recode function (need mutate here too!):

```
# General Format - this is not code!
{data_input} %>%
  mutate({variable_to_fix} = {Variable_fixing}, {old_value} = {new_value},
         {another_old_value} = {new_value})
```

```
data_diet %>%
  mutate(Gender = recode(Gender, M = "Male",
                        m = "Male",
                        Man = "Male",
                        O = "Other",
                        f = "Female",
                        F = "Female")) %>%
  count(Gender, Diet)
```

recode()

```
data_diet %>%  
  mutate(Gender = recode(Gender, M = "Male",  
                           m = "Male",  
                           Man = "Male",  
                           O = "Other",  
                           f = "Female",  
                           F = "Female")) %>%  
  count(Gender, Diet)
```

```
# A tibble: 5 × 3  
  Gender Diet      n  
  <chr>  <chr> <int>  
1 Female A         3  
2 Female B         2  
3 Male   A         1  
4 Male   B         3  
5 Other  B         3
```

Or you can use `case_when()`

The `case_when()` function of `dplyr` can help us to do this as well.

```
# General Format - this is not code!
{data_input} %>%
  mutate({variable_to_fix} = case_when({Variable_fixing}
                                       /some condition/ ~ {value_for_con}))
```

Note that automatically values not reassigned explicitly by `case_when()` will be `NA` unless otherwise specified.

```
data_diet %>%
  mutate(Gender = case_when(Gender == "M" ~ "Male"))
```

```
# A tibble: 12 × 4
  Diet Gender Weight_start Weight_change
<chr> <chr>      <int>      <int>
1 A    <NA>      225         3
2 B    <NA>      105        -3
3 B    <NA>      229        18
4 A    <NA>      110         6
5 B    <NA>      159         2
6 B    Male      199        14
7 A    <NA>      120         5
8 B    <NA>      201        -9
9 B    <NA>      233        -5
10 A   <NA>      108         0
11 B   <NA>      118        12
12 B   <NA>      121         8
```

Use of `case_when()` without automatic NA

```
# General Format - this is not code!  
{data_input} %>%  
  mutate({variable_to_fix} = case_when({Variable_fixing}  
    /some condition/ ~ {value_for_con},  
    TRUE ~ {value_for_not_meeting_condition}))
```

Here we use the original values of `Gender` to replace all values of `Gender` that do not meet the condition `== "M"`.

```
data_diet %>%  
  mutate(Gender = case_when(Gender == "M" ~ "Male",  
    TRUE ~ Gender))
```

```
# A tibble: 12 × 4  
  Diet Gender Weight_start Weight_change  
  <chr> <chr>      <int>      <int>  
1 A     Male      225         3  
2 B     m         105        -3  
3 B     Other      229        18  
4 A     F         110         6  
5 B     Female      159         2  
6 B     Male       199        14  
7 A     f         120         5  
8 B     0         201        -9  
9 B     Man       233        -5  
10 A     f         108         0  
11 B     F         118        12  
12 B     0         121         8
```

More complicated case_when()

```
data_diet %>%  
  mutate(Gender = case_when(  
    Gender %in% c("M", "male", "Man", "m", "Male") ~ "Male",  
    Gender %in% c("F", "Female", "f", "female") ~ "Female",  
    Gender %in% c("O", "Other") ~ "Other"))
```

A tibble: 12 × 4

	Diet	Gender	Weight_start	Weight_change
	<chr>	<chr>	<int>	<int>
1	A	Male	225	3
2	B	Male	105	-3
3	B	Other	229	18
4	A	Female	110	6
5	B	Female	159	2
6	B	Male	199	14
7	A	Female	120	5
8	B	Other	201	-9
9	B	Male	233	-5
10	A	Female	108	0
11	B	Female	118	12
12	B	Other	121	8

Another reason for `case_when()`

`case_when` can do very sophisticated comparisons

```
data_diet <- data_diet %>%  
  mutate(Effect = case_when(Weight_change > 0 ~ "Increase",  
                             Weight_change == 0 ~ "Same",  
                             Weight_change < 0 ~ "Decrease"))  
  
head(data_diet)
```

```
# A tibble: 6 × 5  
  Diet Gender Weight_start Weight_change Effect  
  <chr> <chr>      <int>      <int> <chr>  
1 A    Male        225         3 Increase  
2 B    m          105        -3 Decrease  
3 B    Other        229        18 Increase  
4 A    F           110         6 Increase  
5 B    Female        159         2 Increase  
6 B    M            199        14 Increase
```

```
# A tibble: 4 × 3  
  Diet Effect      n  
  <chr> <chr>   <int>  
1 A    Increase    3  
2 A    Same         1  
3 B    Decrease     3  
4 B    Increase     5
```

Effect of diet A & B on participants

Working with strings

Strings in R

- R can do much more than find exact matches for a whole string!

The **stringr** package

The `stringr` package:

- Modifying or finding **part** or all of a character string
- We will not cover `grep` or `gsub` - base R functions
 - are used on forums for answers
- Almost all functions start with `str_*`

stringr

`str_detect`, and `str_replace` search for matches to argument pattern within each element of a character vector (not data frame or tibble!).

- `str_detect` - returns `TRUE` if pattern is found
- `str_replace` - replaces pattern with replacement

str_detect()

The `string` argument specifies what to check

The `pattern` argument specifies what to check for

```
x<-c("cat", "dog", "mouse")  
str_detect(string = x, pattern = "d")
```

```
[1] FALSE  TRUE  FALSE
```

str_replace()

The `string` argument specifies what to check

The `pattern` argument specifies what to check for

The `replacement` argument specifies what to replace the pattern with

```
x<-c("cat", "dog", "mouse")  
str_replace(string = x, pattern = "d", replacement = "D")
```

```
[1] "cat"    "Dog"    "mouse"
```

Subsetting part of a string

`str_sub()` allows you to subset part of a string

The `string` argument specifies what strings to work with The `start` argument specifies position of where to start

The `end` argument specifies position of where to end

```
x<-c("cat", "dog", "mouse")  
str_sub(string = x, start = 1, end = 2)
```

```
[1] "ca" "do" "mo"
```

filter and stringr functions

```
head(data_diet, n = 4)
```

```
# A tibble: 4 × 5
  Diet Gender Weight_start Weight_change Effect
<chr> <chr>      <int>         <int> <chr>
1 A     Male      225             3 Increase
2 B     m        105            -3 Decrease
3 B     Other     229            18 Increase
4 A     F         110             6 Increase
```

```
data_diet %>%
  filter(str_detect(string = Gender,
                    pattern = "M"))
```

```
# A tibble: 3 × 5
  Diet Gender Weight_start Weight_change Effect
<chr> <chr>      <int>         <int> <chr>
1 A     Male      225             3 Increase
2 B     M        199            14 Increase
3 B     Man      233            -5 Decrease
```

case_when() improved with stringr

```
count(data_diet, Gender)
```

```
# A tibble: 9 × 2
```

	Gender	n
	<chr>	<int>
1	f	2
2	F	2
3	Female	1
4	m	1
5	M	1
6	Male	1
7	Man	1
8	O	2
9	Other	1

```
data_diet %>%
```

```
  mutate(Gender = case_when(  
    Gender %in% c("M", "male", "Man", "m", "Male") ~ "Male",  
    Gender %in% c("F", "Female", "f", "female") ~ "Female",  
    Gender %in% c("O", "Other") ~ "Other"))
```

case_when() improved with stringr

^ indicates the beginning of a character string \$ indicates the end

```
data_diet %>%  
  mutate(Gender = case_when(  
    str_detect(string = Gender, pattern = "^m|^M") ~ "Male",  
    str_detect(string = Gender, pattern = "^f|^F") ~ "Female",  
    str_detect(string = Gender, pattern = "^o|^O") ~ "Other")) %>%  
  count(Gender)
```

```
# A tibble: 3 × 2  
  Gender      n  
  <chr>  <int>  
1 Female      5  
2 Male        4  
3 Other       3
```

Separating and uniting data

What if our data looked like this?

```
diet_comb
```

```
# A tibble: 4 × 2  
  change      n  
  <chr>    <int>  
1 A_Increase    3  
2 A_Same        1  
3 B_Decrease    3  
4 B_Increase    5
```

Separating columns based on a separator

The `separate()` function from `tidyr` can split a column into multiple columns.

The `col` argument specifies what column to work with

The `into` argument specifies names of new columns

The `sep` argument specifies what to separate by

```
diet_comb %>%  
  separate(col = change, into = c("Diet", "Change"), sep = "_" )
```

```
# A tibble: 4 × 3
```

	Diet <chr>	Change <chr>	n <int>
1	A	Increase	3
2	A	Same	1
3	B	Decrease	3
4	B	Increase	5

Uniting columns

The `unite()` function can instead help combine columns.

The `col` argument specifies new column name

The `sep` argument specifies what separator to use when combining

```
# A tibble: 4 × 2
  id visit
<int> <int>
1     1     1
2     2     1
3     3     1
4     4     1
```

```
df_united <- df %>% unite(col = "unique_id", id, visit, sep = "_")
head(df_united, 4)
```

```
# A tibble: 4 × 1
  unique_id
<chr>
1 1_1
2 2_1
3 3_1
4 4_1
```

Summary

- `recode()` can help with simple recoding (not based on condition but simple swap)
- `case_when()` can recode **entire values** based on conditions
 - remember `case_when()` needs `TRUE ~ variable` to keep values that aren't specified by conditions, otherwise will be `NA`
- `stringr` package has great functions for looking for specific **parts of values** especially `filter()` and `str_detect()` combined
 - also has other useful string manipulation functions like `str_replace()` and more!
 - `separate()` can split columns into additional columns
 - `unite()` can combine columns

Extra Slides

String Splitting

- `str_split(string, pattern)` - splits strings up - returns list!

```
library(stringr)
x <- c("I really like writing R code")
df = tibble(x = c("I really", "like writing", "R code programs"))
y <- unlist(str_split(x, " "))
y
```

```
[1] "I"          "really"    "like"      "writing"   "R"         "code"
```

```
length(y)
```

```
[1] 6
```

A bit on Regular Expressions

- <http://www.regular-expressions.info/reference.html>
- They can use to match a large number of strings in one statement
- `.` matches any single character
- `*` means repeat as many (even if 0) more times the last character
- `?` makes the last thing optional
- `^` matches start of vector `^a` - starts with "a"
- `$` matches end of vector `b$` - ends with "b"

Let's look at modifiers for `stringr`

`?modifiers`

- `fixed` - match everything exactly
- `ignore_case` is an option to not have to use `tolower`

Using a fixed expression

One example case is when you want to split on a period ".". In regular expressions . means **ANY** character, so we need to specify that we want R to interpret "." as simply a period.

```
str_split("I.like.strings", ".")
```

```
[[1]]  
[1] "" "" "" "" "" "" "" "" "" "" "" "" "" "" ""
```

```
str_split("I.like.strings", fixed("."))
```

```
[[1]]  
[1] "I"      "like"   "strings"
```

```
str_split("I.like.strings", "\\.")
```

```
[[1]]  
[1] "I"      "like"   "strings"
```

Pasting strings with `paste` and `paste0`

Paste can be very useful for joining vectors together:

```
paste("Visit", 1:5, sep = "_")
```

```
[1] "Visit_1" "Visit_2" "Visit_3" "Visit_4" "Visit_5"
```

```
paste("Visit", 1:5, sep = "_", collapse = "_")
```

```
[1] "Visit_1_Visit_2_Visit_3_Visit_4_Visit_5"
```

```
# and paste0 can be even simpler see ?paste0  
paste0("Visit", 1:5) # no space!
```

```
[1] "Visit1" "Visit2" "Visit3" "Visit4" "Visit5"
```

Comparison of **stringr** to base R -
not covered

Splitting Strings

Substringing

stringr

- `str_split(string, pattern)` - splits strings up - returns list!

Splitting String:

In `stringr`, `str_split` splits a vector on a string into a list

```
library(stringr)
x <- c("I really", "like writing", "R code programs")
y <- str_split(x, pattern = " ") # returns a list
y
```

```
[[1]]
[1] "I"      "really"
```

```
[[2]]
[1] "like"   "writing"
```

```
[[3]]
[1] "R"      "code"   "programs"
```

'Find' functions: stringr compared to base R

Base R does not use these functions. Here is a "translator" of the `stringr` function to base R functions

- `str_detect` - similar to `grep1` (return logical)
- `grep(value = FALSE)` is similar to `which(str_detect())`
- `str_subset` - similar to `grep(value = TRUE)` - return value of matched
- `str_replace` - similar to `sub` - replace one time
- `str_replace_all` - similar to `gsub` - replace many times

Important Comparisons

Base R:

- Argument order is (pattern, x)
- Uses option (fixed = TRUE)

stringr

- Argument order is (string, pattern) aka (x, pattern)
- Uses function fixed(pattern)

some data to work with

```
Sal = read_salaries() # or
```

Showing difference in `str_extract`

`str_extract` extracts just the matched string

```
ss = str_extract(Sal$Name, "Rawling")
```

Warning: Unknown or uninitialised column: `Name`.

```
head(ss)
```

```
character(0)
```

```
ss[ !is.na(ss)]
```

```
character(0)
```

Showing difference in `str_extract` and `str_extract_all`

`str_extract_all` extracts all the matched strings

```
head(str_extract(Sal$AgencyID, "\\d"))
```

```
[1] "0" "2" "6" "9" "4" "9"
```

```
head(str_extract_all(Sal$AgencyID, "\\d"), 2)
```

```
[[1]]  
[1] "0" "3" "0" "3" "1"
```

```
[[2]]  
[1] "2" "9" "0" "4" "5"
```

Using Regular Expressions

- Look for any name that starts with:
 - Payne at the beginning,
 - Leonard and then an S
 - Spence then capital C

```
head(grep("^Payne.*", x = Sal$name, value = TRUE), 3)
```

```
[1] "Payne El, Boaz L"      "Payne El, Jackie"  
[3] "Payne Johnson, Nickole A"
```

```
head(grep("Leonard.?S", x = Sal$name, value = TRUE))
```

```
[1] "Payne, Leonard S"      "Szumlanski, Leonard S"
```

```
head(grep("Spence.*C.*", x = Sal$name, value = TRUE))
```

```
[1] "Spencer, Charles A"  "Spencer, Clarence W" "Spencer, Michael C"
```

Using Regular Expressions: **stringr**

```
head(str_subset( Sal$name, "^Payne.*"), 3)
```

```
[1] "Payne El, Boaz L"      "Payne El, Jackie"  
[3] "Payne Johnson, Nickole A"
```

```
head(str_subset( Sal$name, "Leonard.?S"))
```

```
[1] "Payne, Leonard S"      "Szumlanski, Leonard S"
```

```
head(str_subset( Sal$name, "Spence.*C.*"))
```

```
[1] "Spencer, Charles A"   "Spencer, Clarence W" "Spencer, Michael C"
```

Replace

Let's say we wanted to sort the data set by Annual Salary:

```
class(Sal$AnnualSalary)
```

```
[1] "character"
```

```
sort(c("1", "2", "10")) # not sort correctly (order simply ranks the data)
```

```
[1] "1"  "10" "2"
```

```
order(c("1", "2", "10"))
```

```
[1] 1 3 2
```

Replace

So we must change the annual pay into a numeric:

```
head(Sal$AnnualSalary, 4)
```

```
[1] "$55314.00" "$74000.00" "$64500.00" "$46309.00"
```

```
head(as.numeric(Sal$AnnualSalary), 4)
```

```
Warning in head(as.numeric(Sal$AnnualSalary), 4): NAs introduced by coercion
```

```
[1] NA NA NA NA
```

R didn't like the \$ so it thought turned them all to NA.

`sub()` and `gsub()` can do the replacing part in base R.

Replacing and subbing

Now we can replace the \$ with nothing (used `fixed=TRUE` because \$ means ending):

```
Sal$AnnualSalary <- as.numeric(gsub(pattern = "$", replacement="",  
                                   Sal$AnnualSalary, fixed=TRUE))  
Sal <- Sal[order(Sal$AnnualSalary, decreasing=TRUE), ]  
Sal[1:5, c("name", "AnnualSalary", "JobTitle")]
```

```
# A tibble: 5 × 3
```

	name <chr>	AnnualSalary <dbl>	JobTitle <chr>
1	Mosby, Marilyn J	238772	STATE'S ATTORNEY
2	Batts, Anthony W	211785	Police Commissioner
3	Wen, Leana	200000	Executive Director III
4	Raymond, Henry J	192500	Executive Director III
5	Swift, Michael	187200	CONTRACT SERV SPEC II

Replacing and subbing: **stringr**

We can do the same thing (with 2 piping operations!) in dplyr

```
dplyr_sal = Sal
dplyr_sal = dplyr_sal %>% mutate(
  AnnualSalary = AnnualSalary %>%
    str_replace(
      fixed("$"),
      "" ) %>%
    as.numeric) %>%
  arrange(desc(AnnualSalary))
check_Sal = Sal
rownames(check_Sal) = NULL
all.equal(check_Sal, dplyr_sal)
```

```
[1] TRUE
```

Creating Two-way Tables

A two-way table. If you pass in 2 vectors, `table` creates a 2-dimensional table.

```
tab <- table(c(0, 1, 2, 3, 2, 3, 3, 2, 2, 3),  
             c(0, 1, 2, 3, 2, 3, 3, 4, 4, 3),  
             useNA = "always")  
tab
```

	0	1	2	3	4	<NA>
0	1	0	0	0	0	0
1	0	1	0	0	0	0
2	0	0	2	0	2	0
3	0	0	0	4	0	0
<NA>	0	0	0	0	0	0

Creating Two-way Tables

```
tab_df = tibble(x = c(0, 1, 2, 3, 2, 3, 3, 2, 2, 3),  
                 y = c(0, 1, 2, 3, 2, 3, 3, 4, 4, 3))  
tab_df %>% count(x, y)
```

```
# A tibble: 5 × 3  
      x     y     n  
  <dbl> <dbl> <int>  
1     0     0     1  
2     1     1     1  
3     2     2     2  
4     2     4     2  
5     3     3     4
```

Creating Two-way Tables

```
tab_df %>%  
  count(x, y) %>%  
  group_by(x) %>% mutate(pct_x = n / sum(n))
```

```
# A tibble: 5 × 4  
# Groups:   x [4]  
      x     y     n pct_x  
  <dbl> <dbl> <int> <dbl>  
1     0     0     1     1  
2     1     1     1     1  
3     2     2     2    0.5  
4     2     4     2    0.5  
5     3     3     4     1
```

Creating Two-way Tables

```
library(scales)
tab_df %>%
  count(x, y) %>%
  group_by(x) %>% mutate(pct_x = percent(n / sum(n)))
```

```
# A tibble: 5 × 4
# Groups:   x [4]
      x     y     n pct_x
  <dbl> <dbl> <int> <chr>
1     0     0     1 100%
2     1     1     1 100%
3     2     2     2  50%
4     2     4     2  50%
5     3     3     4 100%
```
