Intro to

R

Subsetting Data in R

Recap

- R functions as a calculator
- Use c() to combine vectors
- Use <- to save (assign) values to objects
- if you don't use <- to reassign objects that you want to modify, they will stay
 the same
- · length(), class(), and str() tell you information about an object
- head() and tail() can also help you inspect an object
- readrhas helpful functions like read_csv() that can help you import data into R

Cheatsheet

Overview

In this module, we will show you how to:

- 1. Look at your data in different ways
- 2. Create a data frame and a tibble
- 3. Create new variables/make rownames a column
- 4. Rename columns of a data frame
- 5. Subset rows of a data frame
- 6. Subset columns of a data frame
- 7. Add/remove new columns to a data frame
- 8. Order the columns of a data frame
- 9. Order the rows of a data frame

Setup

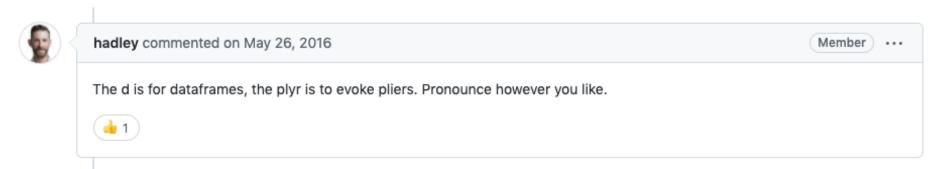

We will largely focus on the dplyr package which is part of the tidyverse.

Some resources on how to use dplyr:

- https://dplyr.tidyverse.org/
- https://cran.r-project.org/web/packages/dplyr/vignettes/dplyr.html
- https://www.opencasestudies.org/

Why dplyr?

The dplyr package is one of the most helpful packages for altering your data to get it into a form that is useful for creating visualizations, summarizing, or more deeply analyzing.

So you can imagine using pliers on your data.

Loading in dplyr and tidyverse

See this website for a list of the packages included in the tidyverse: https://www.tidyverse.org/packages/

library(tidyverse) # loads dplyr and other packages!

Getting data to work with

Here we use one of the datasets that comes with base R called mtcars. We will now create a toy data frame named df using this data. This way we can alter df without worrying about changing mtcars.

```
df <- mtcars # df is a copy of mtcars
head(df) # changing df does **not** change mtcars!</pre>
```

	mpg	cyl	disp	hp	drat	wt	qsec	VS	am	gear	carb
Mazda RX4	21.0	6	160	110	3.90	2.620	16.46	0	1	4	4
Mazda RX4 Wag	21.0	6	160	110	3.90	2.875	17.02	0	1	4	4
Datsun 710	22.8	4	108	93	3.85	2.320	18.61	1	1	4	1
Hornet 4 Drive	21.4	6	258	110	3.08	3.215	19.44	1	0	3	1
Hornet Sportabout	18.7	8	360	175	3.15	3.440	17.02	0	0	3	2
Valiant ·	18.1	6	225	105	2.76	3.460	20.22	1	0	3	1

Checking the data dim()

The dim(), nrow(), and ncol() functions are good options to check the dimensions of your data before moving forward.

```
dim(df) # rows, columns
[1] 32 11
nrow(df) # number of rows
[1] 32
ncol(df) # number of columns
[1] 11
```

Checking the data: glimpse()

In addition to head() and tail(), the glimpse() function of the dplyr package is another great function to look at your data.

glimpse(df)

Checking your data: slice_sample()

What if you want to see the middle of your data? You can use the slice_sample() function of the dplyr package to see a random set of rows. You can specify the number of rows with the n argument or use a proportion with the prop argument.

```
slice_sample(df, n = 3)
                 mpg cyl disp hp drat wt qsec vs am gear carb

	E	00 4	А	05.4	110	0 77	1 510	10 00	1	1		

Keep in mind...

Need to assign the output of the function to keep the result!

```
df_updated <- data.frame(df)
# this would overwrite the existing df object
df<-data.frame(df)</pre>
```

Or create a data frame when reading in the file

Or directly when reading in a csv with the read.csv() function (also base R)

```
# function comes from base R - no package loading required
df_example_readr <- read.csv(file = "documents/data_analysis/data_file.csv")</pre>
```

tibble

We can create a **fancier** version of the previous data frame which can be really helpful.

Creating a tibble

If we would like to create a tibble ("fancy" data frame), we can using the tibble() function.

```
tbl <- tibble(df)
tbl</pre>
```

```
# A tibble: 32 × 11
                                                           cyl disp

                                                                                                                             123
                                                                                                                                                       3.92
                                                                                                                                                                                        3.44
                                                                                                                                                                                                                        18.3
# ... with 22 more rows
```

Note don't necessarily need to use head()- tibbles conveniently print a portion of the data.

tibbles form read_csv()

Alternatively we can read data files using the tidyverse with the read_csv() function of the readr package from the tidyverse to make a tibble.

```
df_example_readr <- read_csv(file = "documents/data_analysis/data_file.csv")</pre>
```

You may start to notice how the tidyverse package work well together!

Summary of tibbles and data frames

Base R:

Using read.csv() and data.frame() you can make data frames

Tidyverse (fancier version):

Using read_csv() and tibble() you can make tibbles

We generally recommend using tibbles, but you can do a lot with data frames too.

Data frames vs tibbles

In the "tidy" data format, rownames are removed. For example, df has each car name as a row name. Here we use the head() function to see the first 2 rows of each using the n argument. In this case we would want to make the rownames a new column first before making into a tibble.

```
head(df, n = 2)
                                                                                  mpg cyl disp hp drat wt gsec vs am gear carb
                                                                                                                     6 160 110 3.9 2.620 16.46 0 1

                                                                                              160
                                                                                                                                 110
                                                                                                                                                                                                                                                                                          0
```

rownames_to_column function

If you run into losing a variable contained in your row names, you can also use rownames_to_column (of tibble package) to add it before turning it into a tibble to keep them:

```
# general format! not code!
{data you are creating or changing} <- # reassign if you want to keep changes
     rownames_to_column({data you are using},
                   {Name of column you are making from rownames})
head(rownames_to_column(df, "car"), n = 2)
         car mpg cyl disp hp drat wt qsec vs am gear carb
    Mazda RX4 21 6 160 110 3.9 2.620 16.46 0 1
2 Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1
head(tibble(rownames_to_column(df, "car")), n = 2)
# A tibble: 2 \times 12
                 cvl disp hp drat wt gsec vs
                                                     am gear ca
 car
             mpg
 1 Mazda RX4 21
                    6 160
                            110 3.9 2.62 16.5
                                                      1
                                                           4
                                                 0
2 Mazda RX4 W... 21 6
                            110
                                 3.9 2.88 17.0
                       160
                                                 (-)
```

Renaming Columns

Renaming Columns of a data frame or tibble

To rename columns in dplyr, you can use the rename function.

For example, let's rename mpg to MPG. Notice the new name is listed **first**!

```
# general format! not code!
{data you are creating or changing} <- rename({data you are using}, {New Name} = {Old name})

df <- rename(df, MPG = mpg)
head(df)

MPG cyl disp hp drat wt qsec vs am gear carb
Mazda RX4 21.0 6 160 110 3.90 2.620 16.46 0 1 4 4
Mazda RX4 Wag 21.0 6 160 110 3.90 2.875 17.02 0 1 4 4
Datsun 710 22.8 4 108 93 3.85 2.320 18.61 1 1 4 1
Hornet 4 Drive 21.4 6 258 110 3.08 3.215 19.44 1 0 3 1
Hornet Sportabout 18.7 8 360 175 3.15 3.440 17.02 0 0 3 2
Valiant 18.1 6 225 105 2.76 3.460 20.22 1 0 3 1
```

Take Care with Column Names

When you can, avoid spaces, special punctuation, or numbers in column names, as these require quotes to refer to them.

See https://jhudatascience.org/intro_to_r/quotes_vs_backticks.html for more guidance.

```
df <- rename(df, MPG! = MPG) # this will cause an error

df_rename <-rename(df, `MPG!` = MPG) # this will work
head(df_rename, 2)</pre>
```

```
MPG! cyl disp hp drat wt qsec vs am gear carb
Mazda RX4 21 6 160 110 3.9 2.620 16.46 0 1 4 4
Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1 4 4
```

You will need to refer to a column like this with most functions.

Take Care with Column Names and Character Strings

These are the conventions, most options will work for most functions.

Backticks are typically for nonstandard variable names:

- those with spaces col 1
- those with punctuation col.1
- those that are just numbers 1
- those that start with numbers 1st col

Single or double quotes are typically used for character strings (data values that has characters):

- "words"
- · "phrases with spaces"
- 'words'
- · 'phrases with spaces'

Be careful about copy pasting code!

Curly quotes will not work!

```
df_rename <-rename(df, 'MPG!' = MPG) # this will cause an error!

df_rename <-rename(df, `MPG!` = MPG) # this will work!

Also true for double quotes

df_rename <-rename(df, "MPG!" = MPG) # this will cause an error!

df_rename <-rename(df, "MPG!" = MPG) # this will work!</pre>
```

Renaming All Columns of a data frame: dplyr

To rename all columns you use the rename_with(). In this case we will use toupper() to make all letters upper case. Could also use tolower() function.

Summary

- · data frames are simpler version of a data table
- tibbles are fancier tidyverse version
- data frames are made with data.frames() and read.csv()
- tibbles are made with tibble() and read_csv() from readr
- If your original data has rownames, you need to use rownames_to_column before converting to tibble
- the rename() function of dplyr can help you rename columns
- avoid using punctuation (except underscores), spaces, and numbers (to start or alone) in column names
- If you must use backticks around those column names
- quotes can be used for character values
- avoid copy and pasting code from other sources quotation marks will change!

Lab Part 1

Class Website Lab

Subsetting Columns

Subset columns of a data frame - tidyverse way:

To grab (or "pull" out) the carb column the tidyverse way we can use the pull function:

pull(df, carb)

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

Subset columns of a data frame: dplyr

The select command from dplyr allows you to subset (still a tibble!)

select(df, mpg)

	mpg
Mazda RX4	21.0
Mazda RX4 Wag	21.0
Datsun 710	22.8
	21.4
Hornet Sportabout	
Valiant	18.1
Duster 360	14.3
	24.4
	22.8
	19.2
	17.8
	16.4
Merc 450SL	17.3
Merc 450SLC	15.2
Cadillac Fleetwood	
Lincoln Continental	
Chrysler Imperial	14.7
Fiat 128	32.4
Honda Civic	30.4
Toyota Corolla	33.9
	21.5
9	15.5
AMC Javelin	15.2
Camaro Z28	13.3
Pontiac Firehird	10 2

Pontiac Firebiro

Subset columns of a data frame: dplyr

Note that if you want the values (not a tibble), use pull - as it pulls out the data:

```
pull(df, mpg)

[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.5 16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.5 15.0 21.4

# pull with select works too!

pull(select(df, mpg))

[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.5 16.6 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.5 16.1 15.0 21.4
```

Select columns of a data frame: dplyr

Chrysler Imperial

The select command from dplyr allows you to subset columns matching patterns:

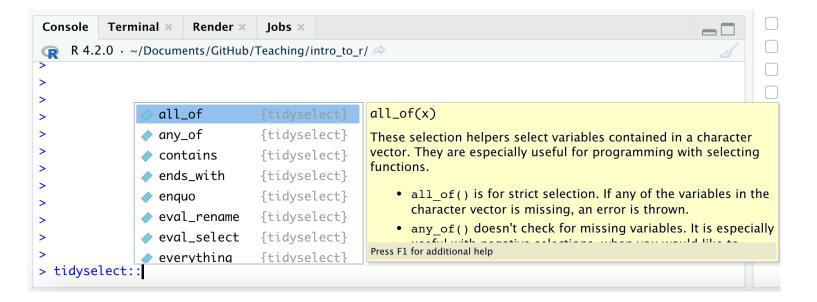

```
head(df, 2)
             mpg cyl disp hp drat wt qsec vs am gear carb
Mazda RX4
                   6 160 110 3.9 2.620 16.46 0 1
             21
Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1
                                                             4
select(df, starts_with("c"))
                   cyl carb
Mazda RX4
                     6
Mazda RX4 Waq
Datsun 710
Hornet 4 Drive
                     8
Hornet Sportabout
                          1
                     6
Valiant
Duster 360
Merc 240D
Merc 230
                     6
Merc 280
Merc 280C
                          3
Merc 450SE
                          3
                     8
Merc 450SL
                          3
                     8
Merc 450SLC
                     8
Cadillac Fleetwood
Lincoln Continental
```

See the Select "helpers"

Here are a few:

```
last_col()
starts_with()
ends_with()
contains() # like searching
```

Type tidyselect:: in the console and see what RStudio suggests:

Summary

- pull() to get values out of a data frame/tibble
- select() is the tidyverse way to get a tibble with only certain columns
- you can select() based on patterns in the column names

Lab Part 2

Class Website Lab

Subsetting Rows

The command in dplyr for subsetting rows is filter.

```
filter(df, mpg > 20)
```

```
disp
                              hp drat
               mpg cyl
                                         wt gsec vs am gear carb
Mazda RX4
                     6 160.0 110 3.90 2.620 16.46
              21.0
                                                      1
                                                           4
Mazda RX4 Waq

              21.4
                     4 121.0 109 4.11 2.780 18.60
```

You can have multiple logical conditions using the following:

- · == : equals to
- !=: not equal to (! : not/negation)
- · > / <: greater than / less than
- >= or <=: greater than or equal to / less than or equal to
- &: AND
- · |: OR

The %in% operator can be used find values from a pre-made list (using c()):

```
filter(df, mpg %in% c(20,21,22))
```

```
mpg cyl disp hp drat wt qsec vs am gear carb
Mazda RX4 21 6 160 110 3.9 2.620 16.46 0 1 4 4
Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1 4 4
```

Toyota Corona 21.5 4 120.1

Fiat X1-9

Lotuc Europa

Porsche 914-2 26.0

27.3 4 79.0

4 120.3

You can filter by two conditions using & or commas (must meet both conditions):

```
filter(df, mpg > 20 & cyl == 4)
              mpg cyl
                      disp hp drat
                                      wt
                                          gsec vs am gear carb

If you want OR statements (meaning the data can meet either condition does not need to meet both), you need to use the pipe | between conditions:

```
filter(df, mpg > 20 | cyl == 4)
```

```
mpg cyl
                        disp
                              hp drat
                                        wt gsec vs am gear carb

which() function

Fiat 128

FAI SF

Instead of removing rows like filter, which() simply shows where the values occur if they pass a specific condition. We will see that this can be helpful later when we want to select and filter in more complicated ways.

```
which(select(df,carb) == 4)
 [1] 1 2 7 10 11 15 16 17 24 29
select(df, carb) == 4
                     carb
Mazda RX4
                     TRUE
Mazda RX4 Waq
                     TRUE
Datsun 710
                    FALSE
Hornet 4 Drive
                    FALSE
Hornet Sportabout
                    FALSE
Valiant
                    FALSE
                    TRUE
Duster 360
                    FALSE
Merc 240D
                    FALSE
Merc 230
Merc 280
                     TRUE

                     TRUE
Merc 450SE
                    FALSE
                    FALSE
Merc 450SL
                    FALSE
Merc 450SLC
Cadillac Fleetwood TRUE
Lincoln Continental TRUE
                                                                        44/78
Chrysler Imperial
                     TRUE
```

distinct() function

To filter for distinct values from a variable, multiple variables, or an entire tibble you can use the distinct() function from the dplyr package.

```
distinct(df, cyl)

Cyl

Mazda RX4 6
Datsun 710 4
Hornet Sportabout 8

distinct(df, cyl, gear)
```

	cyl	gear
Mazda RX4	6	4
Datsun 710	4	4
Hornet 4 Drive	6	3
Hornet Sportabout	8	3
Toyota Corona	4	3
Porsche 914-2	4	5
Ford Pantera L	8	5
Ferrari Dino	6	5

Summary

- filter() can be used to filter out rows based on logical conditions
- == is the same as equivalent to
- & means both conditions must be met to remain after filter()
- I means either conditions needs to be met to remain after filter()
- which() shows you where values meet a condition
- · distinct() helps you filter for unique values

Lab Part 3

Class Website Lab

Combining filter and select

You can combine filter and select to subset the rows and columns, respectively, of a data frame:

```
select(filter(df, mpg > 20 \& cyl == 4), cyl, hp)
```

	cyl	hp
Datsun 710	4	93
Merc 240D	4	62
Merc 230	4	95
Fiat 128	4	66
Honda Civic	4	52
Toyota Corolla	4	65
Toyota Corona	4	97
Fiat X1-9	4	66
Porsche 914-2	4	91
Lotus Europa	4	113
Volvo 142E	4	109

In R, the common way to perform multiple operations is to wrap functions around each other in a "nested" way such as above.

Assigning Temporary Objects

One can also create temporary objects and reassign them:

```
\label{eq:df2} \begin{array}{ll} \text{df2} <- \text{ filter(df, mpg} > 20 \& \text{cyl} == 4) \\ \text{df2} <- \text{ select(df2, cyl, hp)} \\ \\ \text{head(df2,4)} \end{array}
```

	cyl	hp
Datsun 710	4	93
Merc 240D	4	62
Merc 230	4	95
Fiat 128	4	66

Using the pipe (comes with dplyr):

The pipe %>% makes things such as this much more readable. It reads left side "pipes" into right side. RStudio CMD/Ctrl + Shift + M shortcut. Pipe df into filter, then pipe that into select:

```
df %>% filter(mpg > 20 & cyl == 4) %>% select(cyl, hp)
```

	cyl	hp
Datsun 710	4	93
Merc 240D	4	62
Merc 230	4	95
Fiat 128	4	66
Honda Civic	4	52
Toyota Corolla	4	65
Toyota Corona	4	97
Fiat X1-9	4	66
Porsche 914-2	4	91
Lotus Europa	4	113
Volvo 142E	4	109

Adding/Removing Columns

Adding columns to a data frame: dplyr (tidyverse way)

The mutate function in dplyr allows you to add or modify columns of a data frame.

Removing columns of a data frame: dplyr

The **NULL** method is still very common.

The select function can remove a column with minus (-):

```
select(df, - newcol)
```

```
        Mazda RX4

        3
        1
```

Or, you can simply select the columns you want to keep, ignoring the ones you want to remove.

Removing columns in a data frame: dplyr

You can use c() to list the columns to remove.

Remove newcol and drat:

```
select(df, -c("newcol", "drat"))
```

```
mpg cyl disp hp
                                       wt

Ordering columns

The select function can reorder columns.

```
head(df)
select(df, cyl, mpg, wt, car) %>%
head()
```

The select function can reorder columns. Put newcol first, then select the rest of columns:

```
select(df, newcol, everything())
```

```
newcol mpg cyl disp hp drat wt qsec vs am gear carb
Mazda RX4
                                    160 110 3.90 2.620 16.46
                  1.190909 21.0
                                                                 1
                                                                       4
                                                                           4

Summary

- select() and filter() can be combined together
- you can do sequential steps in a few ways:
 - 1. nesting them inside one another using parentheses ()
 - 2. creating intermediate data objects in between
 - 3. using pipes %>%
- select() and relocate() can be used to reorder columns
- arrange() can be used to reorder rows
- can remove rows with filter()
- can remove a column in a few ways:
 - 1. using select() with negative sign in front of column name(s)
 - 2. not selecting it (without negative sign)

Summary cont...

mutate() can be used to create new variables or modify them

A note about base R:

The \$ operator is similar to pull(). This is the base R way to do this:

df\$carb

Although it is easier (for this one task), mixing and matching the \$ operator with tidyverse functions usually doesn't work. Therefore, we want to let you know about it in case you see it, but we suggest that you try working with the tidyverse way.

Adding new columns to a data frame: base R

You can add a new column (or modify an existing one) using the \$ operator instead of mutate.

Just want you to be aware of this as it is very common.

```
df$newcol <- df$wt/2.2
head(df,3)</pre>
```

```
mpg cyl disp hp drat wt qsec vs am gear carb newcol Mazda RX4 21.0 6 160 110 3.90 2.620 16.46 0 1 4 4 1.190909 Mazda RX4 Wag 21.0 6 160 110 3.90 2.875 17.02 0 1 4 4 1.306818 Datsun 710 22.8 4 108 93 3.85 2.320 18.61 1 1 4 1 1.054545
```

Even though \$ is easier for creating new columns, mutate is really powerful, so it's worth getting used to.

Extra Slides - base R subsetting

Subset columns of a data frame:

We can grab the carb column using the \$ operator. This is the base R way to do this:

df\$carb

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

Remove a column in base R

df\$mpg <- NULL

Renaming Columns of a data frame: base R

We can use the **colnames** function to extract and/or directly reassign column names of **df**:

```
colnames(df) # just prints
              "cvl"
                                "hp"
                                         "drat"
                                                 "wt"
                                                           "qsec"
                                                                    "VS"
 [1] "mpg"
                      "disp"
                                "newcol"
 [9] "am"
             "gear" "carb"
colnames(df)[1:3] <- c("MPG", "CYL", "DISP") # reassigns</pre>
head(df)
                  MPG CYL DISP
                                hp drat
                                               qsec vs am gear carb

                                                                  1 1.572727
colnames(df)[1:3] <- c("mpg", "cyl", "disp") #reset - just to keep consistent
```

Renaming Columns of a data frame: base R

We can assign the column names, change the ones we want, and then re-assign the column names:

```
cn <- colnames(df)</pre>
cn[ cn == "drat"] <-"DRAT"</pre>
colnames(df) <- cn</pre>
head(df)
                  mpg cyl disp hp DRAT wt gsec vs am gear carb newcol
Mazda RX4
                 21.0
                           160 110 3.90 2.620 16.46
                                                        1
                                                                  4 1.190909
Mazda RX4 Wag 21.0
                        6 160 110 3.90 2.875 17.02
                                                                  4 1.306818
Datsun 710
                22.8 4 108 93 3.85 2.320 18.61
                                                                  1 1.054545
              21.4 6 258 110 3.08 3.215 19.44
Hornet 4 Drive
                                                                  1 1.461364
Hornet Sportabout 18.7 8 360 175 3.15 3.440 17.02
                                                                  2 1.563636
                 18.1
                        6 225 105 2.76 3.460 20.22
Valiant
                                                                  1 1.572727
colnames(df)[ colnames(df) == "DRAT"] <- "drat" #reset</pre>
```

Subset rows of a data frame with indices:

Let's select **rows** 1 and 3 from **df** using brackets:

```
df[c(1, 3),]
```

```
mpg cyl disp hp drat wt qsec vs am gear carb newcol Mazda RX4 21.0 6 160 110 3.90 2.62 16.46 0 1 4 4 1.190909 Datsun 710 22.8 4 108 93 3.85 2.32 18.61 1 1 4 1 1.054545
```

Subset columns of a data frame:

We can also subset a data frame using the bracket [,] subsetting.

For data frames and matrices (2-dimensional objects), the brackets are [rows, columns] subsetting. We can grab the x column using the index of the column or the column name ("carb")

```
df[, 11]
[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2
df[, "carb"]
[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2
```

Another difference between **tbl** and data frame:

Mostly, tbl (tibbles) are the same as data frames, except they don't print all lines. When subsetting only one column using brackets, a data frame will return the values, but a tbl will return a tbl

```
df[, 1]
 [1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.
[16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.
[31] 15.0 21.4
tbl[, 1]
# A tibble: 32 \times 1
     mpg
   <dbl>
 1 21
2 21
3 22.8
 4 21.4
   18.7
   18.1
   14.3
 8 24.4
 9 22.8
10 19.2
# ... with 22 more rows
```

Subset columns of a data frame:

We can select multiple columns using multiple column names:

```
df[, c("mpg", "cyl")]
```

	mpg	cyl
Mazda RX4	21.0	
Mazda RX4 Wag	21.0	
Datsun 710	22.8	
Hornet 4 Drive	21.4	
Hornet Sportabout	18.7	
Valiant	18.1	
Duster 360	14.3	
Merc 240D	24.4	
Merc 230	22.8	
Merc 280	19.2	
Merc 280C	17.8	
Merc 450SE	16.4	
Merc 450SL	17.3	
Merc 450SLC	15.2	
Cadillac Fleetwood
