Basic R

Common new users frustations

- 1. Different versions of software
- 2. Data type problems (is that a character or a number?)
- 3. Working directory problems: trying to read files that R "can't find"
 - RStudio can help, and so do RStudio Projects
 - discuss in Data Input/Output lecture
- 4. Typos (R is case sensitive, x and X are different)
 - RStudio helps with "tab completion"
 - discussed throughout

Explaining output on slides

In slides, a command (we'll also call them code or a code chunk) will look like this

```
print("I'm code")
[1] "I'm code"
```

And then directly after it, will be the output of the code. So print("I'm code") is the code chunk and [1] "I'm code" is the output.

2 + 2

[1] 4

2 * 4

[1] 8

2 ^ 3

[1] 8

Note, when you type your command, R inherently thinks you want to print the result.

- The R console is a full calculator
- Try to play around with it:
 - +, -, /, * are add, subtract, divide and multiply
 - ^ or ** is power
 - parentheses (and) work with order of operations
 - %% finds the remainder

- 2 + (2 * 3)^2
- [1] 38
- (1 + 3) / 2 + 45
- [1] 47
- 6 / 2 * (1 + 2)
- [1] 9

Try evaluating the following:

- · 2 + 2 * 3 / 4 -3
- . 2 * 3 / 4 * 2
- 2^4 1

Commenting in Scripts

```
# is the comment symbol

# this is a comment

# nothing to its right is evaluated

# this # is still a comment
#### you can use many #'s as you want

1 + 2 # Can be the right of code

[1] 3
```

- You can create variables from within the R environment and from files on your computer
- R uses "<-" to assign values to a variable name (you can also use "=" but this is less accepted)
- · Variable names are case-sensitive, i.e. X and x are different

x <- 2

Χ

[1] 2

x * 4

[1] 8

x + 2

[1] 4

- The most comfortable and familiar class/data type for many of you will be data.frame
- You can think of these as essentially spreadsheets with rows (usually subjects or observations) and columns (usually variables)

- data.frames are somewhat advanced objects in R; we will start with simpler objects;
- Here we introduce "1 dimensional" classes; often referred to as 'vectors'
- Vectors can have multiple sets of observations, but each observation has to be the same class.

```
class(x)

[1] "numeric"

y <- "hello world!"
print(y)

[1] "hello world!"

class(y)

[1] "character"</pre>
```

Try assigning your full name to an R variable called name

Try assigning your full name to an R variable called name

```
name <- "Ava Hoffman"
name
```

[1] "Ava Hoffman"

The 'combine' function

The function **c()** collects/combines/joins single R objects into a vector of R objects. It is mostly used for creating vectors of numbers, character strings, and other data types.

```
x <- c(1, 4, 6, 8)
x

[1] 1 4 6 8

class(x)

[1] "numeric"</pre>
```

The 'combine' function

Try assigning your first and last name as 2 separate character strings into a single vector called name2

The 'combine' function

Try assigning your first and last name as 2 separate character strings into a length-2 vector called name2

```
name2 <- c("Ava", "Hoffman")
name2
[1] "Ava" "Hoffman"</pre>
```

length(): Get or set the length of vectors (including lists) and factors, and of any other R object for which a method has been defined.

```
length(x)

[1] 4

y

[1] "hello world!"

length(y)

[1] 1
```

What do you expect for the length of the name variable? What about the name2 variable?

What are the lengths of each?

What do you expect for the length of the name variable? What about the name2 variable?

What are the lengths of each?

length(name)

[1] 1

length(name2)

[1] 2

You can perform functions to entire vectors of numbers very easily.

- x + 2
- [1] 3 6 8 10
- x * 3
- [1] 3 12 18 24
- x + c(1, 2, 3, 4)
- [1] 2 6 9 12

Lab Part 1

Website

But things like algebra can only be performed on numbers.

```
name2 + 4
```

Error in name2 + 4: non-numeric argument to binary operator

Save these modified vectors as a new vector.

```
y <- x + c(1, 2, 3, 4)
y
[1] 2 6 9 12
```

Note that the R object y is no longer "Hello World!" - It has effectively been overwritten by assigning new data to the variable

You can get more attributes than just class. The function str gives you the structure of the object.

```
str(x)

num [1:4] 1 4 6 8

str(y)

num [1:4] 2 6 9 12
```

This tells you that x is a numeric vector and tells you the length.
