Intro to

R

Subsetting Data in R

Overview

We showed one way to read data into R using read_csv and read.csv. In this module, we will show you how to:

- 1. Select specific elements of an object by an index or logical condition
- 2. Renaming columns of a data.frame
- 3. Subset rows of a data.frame
- 4. Subset columns of a data.frame
- 5. Add/remove new columns to a data.frame
- 6. Order the columns of a data.frame
- 7. Order the rows of a data.frame

Setup

We will show you how to do each operation in base R then show you how to use the dplyr package to do the same operation (if applicable).

Many resources on how to use dplyr exist and are straightforward:

- https://cran.rstudio.com/web/packages/dplyr/vignettes/
- https://stat545-ubc.github.io/block009_dplyr-intro.html
- https://www.opencasestudies.org/

The dplyr package also interfaces well with tibbles (a fancy tidyverse version of a data frame).

Loading in dplyr and tidyverse

```
library(tidyverse)

— Attaching packages — tidyverse 1.3.1

/ ggplot2 3.3.3 / purrr 0.3.4
/ tibble 3.1.1 / stringr 1.4.0
/ tidyr 1.1.3 / forcats 0.5.1
/ readr 1.4.0

— Conflicts — tidyverse_conflicts()
x dplyr::filter() masks stats::filter()
x dplyr::lag() masks stats::lag()
```

Note, when loading dplyr, it says objects can be "masked"/conflicts. That means if you use a function defined in 2 places, it uses the one that is loaded in **last**.

Loading in dplyr and tidyverse

For example, if we print filter, then we see at the bottom namespace:dplyr, which means when you type filter, it will use the one from the dplyr package.

filter function (.data, ..., .preserve = FALSE) { UseMethod("filter") } <bytecode: 0x7ff25f9ef688> <environment: namespace:dplyr>

Loading in dplyr and tidyverse

A filter function exists by default in the stats package, however. If you want to make sure you use that one, you use PackageName::Function with the colon-colon ("::") operator.

stats::filter

This is important when loading many packages, and you may have some conflicts/masking.

Creating a data. frame to work with

Here we use one of the datasets that comes with the jhur package called jhu_cars, which is a (copy of another called mtcars). We will now create a toy data.frame named af using this data:

Creating a data. frame to work with

If we would like to create a tibble ("fancy" data.frame), we can using the as.tbl (from thedplyrpackage) or as_tibble (from the tibble package) functions.

```
tbl = as tibble(df)
tbl
# A tibble: 32 x 12
                   cyl disp
  car
              mpg
                             hp drat
                                       wt
                                           qsec
                                                 VS
                                                      am
                                                          gear
  1 Mazda RX4
             21
                       160
                             110
                                 3.9
                                      2.62
                                           16.5
2 Mazda RX4 ... 21
                                      2.88
                      160
                             110
                                3.9

10 Merc 280
         19.2
                    6 168.
                                3.92
                                      3.44
                                                            4
                             123
                                           18.3
# ... with 22 more rows
```

No rownames in tibbles!

In the "tidy" data format, all information of interest is a variable (not a name). **as of tibble 2.0, rownames are removed**. For example, mtcars has each car name as a row name. Here we use the head() function to see the first 2 rows of each. In this case we would want to make the rownames a new column first before making into a tibble.

```
head (mtcars, 2)
          mpg cyl disp hp drat wt gsec vs am gear carb
          21
              6 160 110 3.9 2.620 16.46 0 1
Mazda RX4
Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1
head(as tibble(mtcars), 2)
# A tibble: 2 \times 11
  mpg cyl disp hp drat wt gsec
                                      am gear carb
                                  VS
 21
        6 160
                110
                  3.9 2.62 16.5
                                   0
                110
                  3.9
                       2.88 17.0
      6 160
                                   ()
```

Renaming Columns

Renaming Columns of a data.frame: dplyr

To rename columns in dplyr, you use the rename command.

For example, let's rename mpg to MPG. Notice the new name is listed first!

Valiant 18.1 6 225 105 2.76 3.460 20.22 1 0

Renaming All Columns of a data. frame: dplyr

To rename all columns you use the rename_all command (with a function). In this case we will use toupper() to make all letters upper case. Could also use tolower() function.

```
df_upper = dplyr::rename_all(df, toupper)
head(df_upper, 3)

CAR MPG CYL DISP HP DRAT WT QSEC VS AM GEAR CARB
1    Mazda RX4 21.0   6  160 110 3.90 2.620 16.46   0   1   4   4
2  Mazda RX4 Wag 21.0   6  160 110 3.90 2.875 17.02   0   1   4   4
3    Datsun 710 22.8   4  108  93 3.85 2.320 18.61   1   1   4   1

df = dplyr::rename_all(df, tolower)
head(df, 3)

car mpg cyl disp hp drat wt qsec vs am gear carb
1    Mazda RX4 21.0   6  160 110 3.90 2.620 16.46   0   1   4   4
2  Mazda RX4 Wag 21.0   6  160 110 3.90 2.875 17.02   0   1   4   4
3    Datsun 710 22.8   4  108  93 3.85 2.320 18.61   1   1   4   1
```

Lab Part 1

Website

Subsetting Columns

Subset columns of a data. frame:

We can grab the carb column using the \$ operator. This is the base R way to do this:

df\$carb

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

Subset columns of a data.frame - tidyverse way:

To grab the carb column the tidyverse way we can use the pull function:

```
pull(df, carb)
```

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

Subset columns of a data. frame: dplyr

23 15.2

24 13.3

The select command from dplyr allows you to subset (gives a tibble!)

```
select(df, mpg)
   mpg
  21.0
  21.0
  22.8
4 21.4
  18.7
6 18.1
7 14.3
8 24.4
  22.8
10 19.2
11 17.8
12 16.4
13 17.3
14 15.2
15 10.4
16 10.4
17 14.7
18 32.4
19 30.4
20 33.9
21 21.5
22 15.5
```

Subset columns of a data. frame: dplyr

Note that if you want a single vector (not a tibble), use pull or \$:

```
pull(df, mpg)

[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.
[16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.
[31] 15.0 21.4

# pull with select works too!

pull(select(df,mpg))

[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.
[16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.
[31] 15.0 21.4
```

Select columns of a data. frame: dplyr

22 15.5

23 15.2

The select command from dplyr allows you to subset columns matching strings:

```
select (df, mpg, cyl)
   mpg cyl
  21.0
  21.0
  22.8
  21.4
  18.7
6 18.1
 14.3
8 24.4
9 22.8
10 19.2
11 17.8
12 16.4
13 17.3
14 15.2
15 10.4
16 10.4
17 14.7
18 32.4
19 30.4
20 33.9
21 21.5
```

See the Select "helpers"

Run the command:

```
??tidyselect::select_helpers
```

Here are a few:

```
one_of() # if they exist
last_col()
ends_with()
contains() # like searching
```

Lab Part 2

Website

Subsetting Rows

The command in dplyr for subsetting rows is filter. Try ?filter

```
filter(df, mpg > 20)
```

```
car mpg cyl disp hp drat
                                           wt qsec vs am qear carb
       Mazda RX4 21.0
                        6 160.0 110 3.90 2.620 16.46
1
                                                            4
2
   Mazda RX4 Wag 21.0 6 160.0 110 3.90 2.875 17.02
3
      Datsun 710 22.8 4 108.0
                                93 3.85
                                   3.08
  Hornet 4 Drive 21.4 6 258.0 110
5
       Merc 240D 24.4 4 146.7 62 3.69 3.190 20.00
6
        Merc 230 22.8 4 140.8 95 3.92 3.150 22.90
        Fiat 128 32.4 4 78.7 66 4.08 2.200 19.47
     Honda Civic 30.4 4 75.7 52 4.93 1.615 18.52
                       4 71.1 65 4.22 1.835 19.90
  Toyota Corolla 33.9
10
   Toyota Corona 21.5
                        4 120.1 97 3.70 2.465 20.01
       Fiat X1-9 27.3
11
                        4 79.0 66 4.08
                                       1.935
  Porsche 914-2 26.0
                      4 120.3 91 4.43 2.140
   Lotus Europa 30.4 4 95.1 113 3.77 1.513 16.90
13
                      4 121.0 109 4.11 2.780 18.60
      Volvo 142E 21.4
14
```

Note, no \$ or subsetting is necessary. R "knows" mpg refers to a column of df.

You can have multiple logical conditions using the following:

- · ==: equals to
- !: not/negation
- · !=: not equal to
- · > / <: greater than / less than
- >= or <=: greater than or equal to / less than or equal to
- · &:AND
- · |: OR

The %in% operator can be used find values from a pre-made list (using c()):

```
filter(df, mpg %in% c(20,21,22))

car mpg cyl disp hp drat wt qsec vs am gear carb

1 Mazda RX4 21 6 160 110 3.9 2.620 16.46 0 1 4 4

2 Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1 4 4
```

By default, you can separate conditions by commas, and filter assumes these statements are joined by &:

```
filter(df, mpg > 20 \& cyl == 4)
                  mpg cyl disp hp drat wt qsec vs am gear carb
      Datsun 710 22.8 4 108.0 93 3.85 2.320
                                               18.61
       Merc 240D 24.4 4 146.7 62 3.69 3.190
                                               20.00
        Merc 230 22.8 4 140.8 95 3.92 3.150
        Fiat 128 32.4 4 78.7 66 4.08
                                         2.200
     Honda Civic 30.4 4 75.7 52 4.93 1.615 18.52
  Toyota Corolla 33.9 4 71.1 65 4.22 1.835 19.90
   Toyota Corona 21.5 4 120.1 97 3.70 2.465 20.01
       Fiat X1-9 27.3 4 79.0 66 4.08 1.935
   Porsche 914-2 26.0 4 120.3 91 4.43 2.140
  Lotus Europa 30.4 4 95.1 113 3.77 1.513 16.90
Volvo 142E 21.4 4 121.0 109 4.11 2.780 18.60
10
11
filter(df, mpg > 20, cyl == 4, mpg != 22.8)
                         disp
                                hp drat
                                               qsec vs am gear carb
                 mpg cyl
                                        wt
            car
      Merc 240D 24.4
                       4 146.7
                                62 3.69 3.190 20.00
                                                        \left(\right)
       Fiat 128 32.4 4 78.7
                                66 4.08 2.200 19.47
                     4 75.7
    Honda Civic 30.4
                                52 4.93 1.615 18.52
 Toyota Corolla 33.9 4 71.1 65 4.22 1.835 19.90
  Toyota Corona 21.5 4 120.1 97 3.70 2.465 20.01 1 0
5
      Fiat X1-9 27.3 4 79.0 66 4.08 1.935 18.90
6
  Porsche 914-2 26.0 4 120.3 91 4.43 2.140 16.70
                                                                     26/58
```

If you want OR statements, you need to do the pipe | explicitly:

```
filter(df, mpg > 20 | cyl == 4)
```

```
car mpg cyl disp hp drat

Lab Part 3

Website

Combining filter and select

You can combine filter and select to subset the rows and columns, respectively, of a data.frame:

```
select(filter(df, mpg > 20 \& cyl == 4), cyl, hp)
```

```
cyl hp
1 4 93
2 4 62
3 4 95
4 66
5 4 52
6 4 65
7 4 97
8 4 66
9 4 91
10 4 113
11 4 109
```

In R, the common way to perform multiple operations is to wrap functions around each other in a nested way such as above.

Assigning Temporary Objects

One can also create temporary objects and reassign them:

```
df2 = filter(df, mpg > 20 & cyl == 4)
df2 = select(df2, cyl, hp)

head(df2,4)

cyl hp
1     4 93
2     4 62
3     4 95
4     4 66
```

Using the pipe (comes with dplyr):

Recently, the pipe %>% makes things such as this much more readable. It reads left side "pipes" into right side. RStudio CMD/Ctrl + Shift + M shortcut. Pipe df into filter, then pipe that into select:

```
df %>% filter(mpg > 20 & cyl == 4) %>% select(cyl, hp)
```

```
cyl hp
1 4 93
2 4 62
3 4 95
4 66
5 4 65
7 4 97
8 4 66
9 4 91
10 4 113
11 4 109
```

Adding/Removing Columns

Adding new columns to a data. frame: base R

You can add a new column, called newcol to df, using the \$ operator:

```
df$newcol = df$wt/2.2
head(df,3)

car mpg cyl disp hp drat wt qsec vs am gear carb newcol
1 Mazda RX4 21.0 6 160 110 3.90 2.620 16.46 0 1 4 4 1.190909
2 Mazda RX4 Wag 21.0 6 160 110 3.90 2.875 17.02 0 1 4 4 1.306818
3 Datsun 710 22.8 4 108 93 3.85 2.320 18.61 1 1 4 1 1.054545
```

Adding columns to a data.frame: dplyr(tidyverse way)

The \$ method is very common.

The mutate function in dplyr allows you to add or replace columns of a data.frame:

```
df = mutate(df, newcol = wt/2.2)

car mpg cyl disp hp drat wt qsec vs am gear carb newcol

Mazda RX4 21 6 160 110 3.9 2.620 16.46 0 1 4 4 1.190909

Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1 4 4 1.306818
```

Creating conditional variables

One frequently-used tool is creating variables with conditions.

A general function for creating new variables based on existing variables is the ifelse() function, which "returns a value with the same shape as test which is filled with elements selected from either yes or no depending on whether the element of test is TRUE or FALSE."

```
ifelse(test, yes, no)

# test: an object which can be coerced
    to logical mode.

# yes: return values for true elements of test.
# no: return values for false elements of test.
```

Adding columns to a data. frame: dplyr

Combined with ifelse (condition, TRUE, FALSE), it can give you:

[1] "Low" "Low" "Medium" "Medium" "Medium"

Adding columns to a data. frame: dplyr

Alternatively, case_when provides a clean syntax as well:

Removing columns of a data.frame: base R

You can remove a column by assigning to NULL:

```
df$newcol = NULL
head(df)
```

Removing columns of a data. frame: dplyr

The NULL method is still very common.

The select function can remove a column with minus (-):

```
select(df, -newcol)
                   mpg cyl disp hp drat wt qsec vs am gear carb disp ca
         Mazda RX4 21.0 6 160 110 3.90 2.620 16.46 0
                                                           4
    Mazda RX4 Wag 21.0
                        6 160 110 3.90 2.875 17.02 0 1
        Datsun 710 22.8 4 108 93 3.85 2.320 18.61 1 1
    Hornet 4 Drive 21.4 6 258 110 3.08 3.215 19.44 1 0
                                                                  Mediı
 Hornet Sportabout 18.7 8 360 175 3.15 3.440 17.02 0 0
                                                                  Mediı
          Valiant 18.1 6 225 105 2.76 3.460 20.22
                                                                   Mediu
 disp cat2
1
       Low
2
       Low
3
       Low
4
   Medium
   Medium
    Medium
```

Or, you can simply select the columns you want to keep, ignoring the ones you want to remove.

Removing columns to a data. frame: dplyr

You can use c() to list the columns to remove.

Remove newcol and drat:

22

```
select(df, -c("newcol", "drat"))
```

Dodge Challenger 15.5

```

Ordering columns

Ordering the columns of a data. frame: dplyr

The select function can reorder columns. Put newcol first, then select the rest of columns:

```
select(df, newcol, everything())
   newcol
                             mpg cyl disp
                                          hp drat
                                                          qsec vs am gear car
                        car

                                                                          48/582
24
                                         95 3.92 3.150 22.90
              Merc 230 22.8
```

Transmutation

The transmute function in dplyr combines both the mutate and select functions. One can create new columns and keep the only the columns wanted:

```
transmute (df, newcol2 = wt/2.2, mpg, hp)
     newcol2
              mpg
  1.1909091
  1.3068182
  1.0545455 22.8
  1.4613636 21.4 110
  1.5636364 18.7
  1,4500000
  1.5636364
11 1.5636364 17.8
12 1.8500000
13 1.6954545
14 1.7181818
15 2.3863636
  2.4654545
   2.4295455
18 1.0000000
                   66
                   52
   0.7340909
             30.4
20 0.8340909
                   65
21 1.1204545
                   97
22 1.6000000 15.5
23 1.5613636 15.2 150
```

Renaming Columns of a data. frame: base R

We can use the colnames function to extract and/or directly reassign column names of df:

```
colnames (df) # just prints
                           "cyl"
                                            "disp"
                                                         "hp"
                  "mpq"
                                                                      "drat"
 [1] "car"
[7] "wt" "qsec" "vs"
[13] "newcol" "disp_cat" "disp_cat2"
                                            "am"
                                                         "gear"
                                                                      "carb"
colnames(df)[1:3] = c("MPG", "CYL", "DISP") # reassigns

Renaming Columns of a data.frame: base R

We can assign the column names, change the ones we want, and then re-assign the column names:

```
cn = colnames(df)
cn[ cn == "drat"] = "DRAT"
colnames(df) = cn
head (df)
                      mpg cyl disp disp hp DRAT wt qsec vs am gear carb
      Mazda RX4 21.0 6 160 110 3.90 2.620 16.46 0 1
Mazda RX4 Wag 21.0 6 160 110 3.90 2.875 17.02 0 1
Datsun 710 22.8 4 108 93 3.85 2.320 18.61 1 1
1

      Mazda RX4 Wag 21.0
      6
      160 110 3.90 2.875 17.02 0 1
      4

      Datsun 710 22.8
      4
      108 93 3.85 2.320 18.61 1 1
      4

      Hornet 4 Drive 21.4
      6

colnames(df)[ colnames(df) == "DRAT"] = "drat" #reset
```

Subset rows of a data. frame with indices:

Let's select **rows** 1 and 3 from df using brackets:

Subset columns of a data.frame:

We can also subset a data.frame using the bracket [,] subsetting.

For data.frames and matrices (2-dimensional objects), the brackets are [rows, columns] subsetting. We can grab the x column using the index of the column or the column name ("carb")

Biggest difference between tbl and data.frame:

Mostly, tbl (tibbles) are the same as data.frames, except they don't print all lines. When subsetting only one column using brackets, a data.frame will return a vector, but a tbl will return a tbl

```
df[, 1]
 [1] "Mazda RX4"
                            "Mazda RX4 Waq"
                                                   "Datsun 710"
                                                   "Valiant"
                            "Hornet Sportabout"
 [4] "Hornet 4 Drive"
 [7] "Duster 360"
                            "Merc 240D"
                                                   "Merc 230"

                            "Volvo 142E"
tbl[, 1]
# A tibble: 32 x 1
```

- 2 Mazda RX4 Waq
- 3 Datsun 710
- 4 Hornet 4 Drive
- 5 Hornet Sportabout

Subset columns of a data. frame:

We can select multiple columns using multiple column names:

```
df[, c("mpg", "cyl")]
                    mpg cyl
             Mazda RX4 21.0
1
         Mazda RX4 Waq 21.0
3
            Datsun 710 22.8
4
        Hornet 4 Drive 21.4
5
6
7
8
     Hornet Sportabout 18.7
                Valiant 18.1
            Duster 360 14.3
             Merc 240D 24.4
9
              Merc 230 22.8
              Merc 280 19.2
             Merc 280C 17.8
11
12
            Merc 450SE 16.4
13
            Merc 450SL 17.3
```

Merc 450SLC 15.2

14

19 Honda Civic 30.4

Toyota Corolla 33.9
Toyota Corona 21.5

22 Dodge Challenger 15.5

23 AMC Javelin 15.2 24 Camaro Z28 13.3

57/58

No rownames in tibbles!

If you run into losing a variable contained in your row names, use rownames to column to add it before turning it into a tibble to keep them:
