Intro to R

Data Summarization

Part 1: Numeric / continuous data

Data Summarization

- Basic statistical summarization
 - mean(x): takes the mean of x
 - sd(x): takes the standard deviation of x
 - median(x): takes the median of x
 - quantile(x): displays sample quantiles of x. Default is min, IQR, max
 - range(x): displays the range. Same as c(min(x), max(x))
 - sum(x): sum of x
 - max(x): maximum value in x
 - min(x): minimum value in x
- all have the na.rm = argument for missing data

Statistical summarization

The vector getting summarized goes inside the parentheses:

```
x <- c(1, 5, 7, 4, 2, 8)
mean(x)

[1] 4.5

range(x)

[1] 1 8

sum(x)

[1] 27</pre>
```

Statistical summarization

Note that many of these functions have additional inputs regarding missing data, typically requiring the na.rm argument ("remove NAs").

```
x < -c(1, 5, 7, 4, 2, 8, NA)
mean(x)
[1] NA
mean(x, na.rm = TRUE)
[1] 4.5
quantile(x)
Error in quantile.default(x): missing values and NaN's not allowed if 'na.rm' is FALSE
quantile(x, na.rm = TRUE)
 0% 25% 50% 75% 100%
 1.0 2.5 4.5 6.5 8.0
```

Statistical summarization

You can only do summarization on numeric or logical types. Not characters.

```
x <- c(1, 5, 7, 4, 2, 8)
sum(x)

[1] 27

z <- c("hello", "goodbye")
sum(z)</pre>
```

Error in sum(z): invalid 'type' (character) of argument

But how do we do this on dataframes?

First we will need to learn about something called the "pipe".

The pipe is this operator in R:

%>%

It tells R to "pipe" the dataset on the left into the next function.

Using the pipe %>%

states <- read_csv("https://hutchdatascience.org/SeattleStatSummer_R/data/states.csv")
states %>% head() # Same as head(states)!

```
# A tibble: 6 \times 14
 entity state_abb state_area_sq_mil... state_division state_region population
 <chr>
                                    <dbl> <chr>
                                                        <chr>
                                                                          <dbl>
            <chr>
1 Alabama
                                    51609 East South Ce... South
                                                                        4903185
            AL
2 Alaska
                                   589757 Pacific
                                                                         731545
            ΑK
                                                       West
3 Arizona
                                   113909 Mountain West
                                                                        7278717
            ΑZ
4 Arkansas
            AR
                                    53104 West South Ce... South
                                                                        3017804
5 California CA
                                                    West
                                   158693 Pacific
                                                                        39512223
6 Colorado
                                   104247 Mountain
                                                       West
                                                                         5758736
# ... with 8 more variables: births_in_2021 <dbl>, fertility_rate_per_1000 <dbl>,
   cesarean_percent <dbl>, life_expect <dbl>, cancer_rate_per_100000 <dbl>,
#
   cancer_mortality <dbl>, Administered_Dose1_Pop_Pct <dbl>,
#
   Series Complete Pop Pct <dbl>
```

States data

colnames() will show us the column names.

colnames(states)

States data

We can also use the pipe:

states %>% colnames()

Summarizing the data

Summarize the data: summarize() function

summarize creates a summary table of a column you're interested in.

```
# General format - Not the code!
{data to use} %>%
  summarize({summary column name} = {operator(source column)})
```

Summarize the data: dplyr summarize() function

summarize creates a summary table of a column you're interested in.

What if there are NAs in my data?

```
states %>%
 summarize(mean_population = mean(cesarean_percent))
# A tibble: 1 × 1
 mean_population
            <dbl>
1
              NA
states %>%
 summarize(mean_population = mean(cesarean_percent, na.rm = TRUE))
# A tibble: 1 × 1
 mean_population
            <dbl>
1
            30.9
add na.rm = TRUE.
```

Summarize the data: dplyr summarize() function

summarize() can do multiple operations at once. Separate by a comma.
Breaking line between these keeps things tidy!

summary() Function

Using summary() can give you rough snapshots of each numeric column (character columns are skipped):

summary(states)

```
entity
                    state_abb
                                      state_area_sq_miles state_division
Length:52
                  Length:52
                                      Min.
                                                  68
                                                         Length:52

       :2
                                                               :2
```

16/34

Let's practice!

Practice

Modify the code below from the states dataset to summarize() the fertility_rate_per_1000 column. Find the mean, min, and max.

```
states %>%

summarize(___ = mean(___),
    __ = min(___),
    __ = max(___))
```

Practice

Modify the code below from the states dataset to summarize() the fertility_rate_per_1000 column. Find the mean, min, and max.

Summary Part 1

- don't forget the na.rm = TRUE argument!
- summary(x): quantile information
- summarize: creates a summary table of columns of interest

Part 2: Categorical data

count function

Use count to return the number of rows of data.

count function

Use **count** to return a frequency table of unique elements of a category (column).

states %>% count(state_region)

count function

Multiple columns listed further subdivides the count.

states %>% count(state_region, state_division)

```
# A tibble: 10 \times 3
   state_region state_division
                                        n
   <chr>
                 <chr>
                                    <int>
 1 North Central East North Central
                                        5
 2 North Central West North Central
 3 Northeast Middle Atlantic
                                        3
 4 Northeast
             New England
 5 South
                 East South Central
 6 South
                 South Atlantic
                                        9
 7 South
                West South Central
                 Mountain
 8 West
                                        8
 9 West
                 Pacific
10 <NA>
                 <NA>
```

Grouping

Perform Operations By Groups: dplyr

group_by allows you group the data set by variables/columns you specify:

Regular data states

```
# A tibble: 52 × 14
  entity state abb state area sq m... state division state region population
  <chr>
              <chr>
                                   <dbl> <chr>
                                                        <chr>
                                                                         <dbl>
 1 Alabama
                                   51609 East South Ce... South
                                                                       4903185
              AL
 2 Alaska
              AK
                                  589757 Pacific West
                                                                        731545
 3 Arizona
              ΑZ
                                  113909 Mountain West
                                                                       7278717
 4 Arkansas
              AR
                                   53104 West South Ce... South
                                                                       3017804
 5 California CA
                                  158693 Pacific
                                                   West
                                                                      39512223
 6 Colorado
                                  104247 Mountain
                                                  West

Perform Operations By Groups: dplyr

group_by allows you group the data set by variables/columns you specify:

```
states grouped <- states %>% group by(state region)
states grouped
# A tibble: 52 × 14
# Groups: state region [5]
  entity
              state_abb state_area_sq_m... state_division state_region population
   <chr>
              <chr>
                                   <dbl> <chr>
                                                        <chr>
                                                                          <dbl>
 1 Alabama
                                   51609 East South Ce... South
              AL
                                                                        4903185

   Administered Dose1 Pop Pct <dbl>, Series Complete Pop Pct <dbl>
```

Summarize the grouped data

It's grouped! Grouping doesn't change the data in any way, but how **functions operate on it**. Now we can summarize **population** by group:

```
states_grouped %>% summarize(total_population = sum(population))
```

Use the pipe to string these together!

Pipe states into group_by, then pipe that into summarize:

```
states %>%
 group_by(state_region) %>%
  summarize(total_population = sum(population))
# A tibble: 5 \times 2
 state_region total_population
 <chr>
                          <dbl>
1 North Central 68329004
2 Northeast
              55982803
3 South
                      125580448
4 West
                      78347268
5 <NA>
                        3193694
```

Let's practice!

Practice

Modify the code to group by state_region and summarize by average fertility_rate_per_1000.

```
states %>%
group_by(___) %>%
summarize(___ = mean(___))
```

Practice

Modify the code to group by state_region and summarize by average fertility_rate_per_1000.

```
states %>%
 group_by(state_region) %>%
  summarize(avg_fert = mean(fertility_rate_per_1000))
# A tibble: 5 \times 2
 state_region avg_fert
                  <dbl>
 <chr>
1 North Central 60.1
                51.2
2 Northeast
                58.0
3 South
              56.3
4 West
5 <NA>
                   30.8
```

Counting

n() can also give you the sample size per group (NAs included).

```
states %>%
 group_by(state_region) %>%
  summarize(total_population = sum(population),
            sample_size = n())
# A tibble: 5 \times 3
  state_region total_population sample_size
 <chr>
                          <dbl>
                                      <int>
1 North Central
                     68329004
                                         12
2 Northeast
                   55982803
                                          9
3 South
                      125580448
                                         17
4 West
                      78347268
                                         13
5 <NA>
                        3193694
                                          1
```

Summary

- don't forget the na.rm = TRUE argument!
- summary(): quantile information
- summarize: creates a summary table of columns of interest
- count(x): what unique values do you have?
- group_by(x): changes all subsequent functions
 - combine with summarize() to get statistics per group
- summarize() with n() gives the sample size (NAs included)
