# Intro to

R

Subsetting Data in R

# Recap

- R functions as a calculator
- Use c() to combine vectors
- Use <- to save (assign) values to objects</li>
- if you don't use <- to reassign objects that you want to modify, they will stay
  the same</li>
- · length(), class(), and str() tell you information about an object
- head() and tail() can also help you inspect an object
- readrhas helpful functions like read\_csv() that can help you import data into R

Cheatsheet

### Overview

In this module, we will show you how to:

- 1. Look at your data in different ways
- 2. Create a data frame and a tibble
- 3. Create new variables/make rownames a column
- 4. Rename columns of a data frame
- 5. Subset rows of a data frame
- 6. Subset columns of a data frame
- 7. Add/remove new columns to a data frame
- 8. Order the columns of a data frame
- 9. Order the rows of a data frame

# Setup

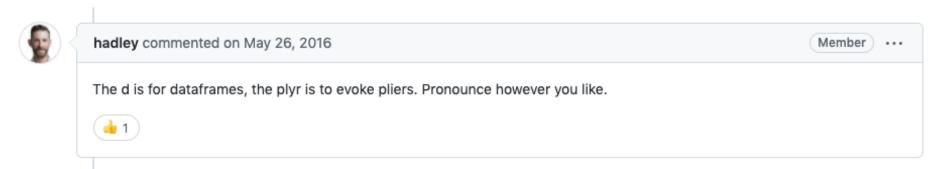

We will largely focus on the dplyr package which is part of the tidyverse.

### Some resources on how to use dplyr:

- https://dplyr.tidyverse.org/
- https://cran.r-project.org/web/packages/dplyr/vignettes/dplyr.html
- https://www.opencasestudies.org/

# Why dplyr?

The dplyr package is one of the most helpful packages for altering your data to get it into a form that is useful for creating visualizations, summarizing, or more deeply analyzing.

So you can imagine using pliers on your data.

# Loading in dplyr and tidyverse

See this website for a list of the packages included in the tidyverse: https://www.tidyverse.org/packages/

library(tidyverse) # loads dplyr and other packages!

# Getting data to work with

Here we use one of the datasets that comes with base R called mtcars. We will now create a toy data frame named df using this data. This way we can alter df without worrying about changing mtcars.

```
df <- mtcars # df is a copy of mtcars
head(df) # changing df does **not** change mtcars!</pre>
```

|                   | mpg  | cyl | disp | hp  | drat | wt    | qsec  | VS | am | gear | carb |
|-------------------|------|-----|------|-----|------|-------|-------|----|----|------|------|
| Mazda RX4         | 21.0 | 6   | 160  | 110 | 3.90 | 2.620 | 16.46 | 0  | 1  | 4    | 4    |
| Mazda RX4 Wag     | 21.0 | 6   | 160  | 110 | 3.90 | 2.875 | 17.02 | 0  | 1  | 4    | 4    |
| Datsun 710        | 22.8 | 4   | 108  | 93  | 3.85 | 2.320 | 18.61 | 1  | 1  | 4    | 1    |
| Hornet 4 Drive    | 21.4 | 6   | 258  | 110 | 3.08 | 3.215 | 19.44 | 1  | 0  | 3    | 1    |
| Hornet Sportabout | 18.7 | 8   | 360  | 175 | 3.15 | 3.440 | 17.02 | 0  | 0  | 3    | 2    |
| Valiant           | 18.1 | 6   | 225  | 105 | 2.76 | 3.460 | 20.22 | 1  | 0  | 3    | 1    |

# Checking the data dim()

The dim(), nrow(), and ncol() functions are good options to check the dimensions of your data before moving forward.

```
dim(df) # rows, columns

[1] 32 11

nrow(df) # number of rows

[1] 32

ncol(df) # number of columns

[1] 11
```

# Checking the data: glimpse()

In addition to head() and tail(), the glimpse() function of the dplyr package is another great function to look at your data.

### glimpse(df)

# Checking your data: slice\_sample()

What if you want to see the middle of your data? You can use the slice\_sample() function of the dplyr package to see a random set of rows. You can specify the number of rows with the n argument or use a proportion with the prop argument.

```
slice_sample(df, n = 3)
                 mpg cyl disp hp drat wt qsec vs am gear carb

# Keep in mind...

Need to assign the output of the function to keep the result!

```
df_updated <- data.frame(df)
# this would overwrite the existing df object
df <- data.frame(df)</pre>
```

# Or create a data frame when reading in the file

Or directly when reading in a csv with the read.csv() function (also base R)

```
# function comes from base R - no package loading required
df_example_readr <- read.csv(file = "documents/data_analysis/data_file.csv")</pre>
```

# tibble

We can create a **fancier** version of the previous data frame which can be really helpful.

# Creating a tibble

If we would like to create a tibble ("fancy" data frame), we can using the tibble() function.

```
tbl <- tibble(df)
tbl</pre>
```

```
# A tibble: 32 × 11

                                                                                                                              123
                                                                                                                                                         3.92
                                                                                                                                                                                          3.44
                                                                                                                                                                                                                          18.3
# ... with 22 more rows
```

Note don't necessarily need to use head()- tibbles conveniently print a portion of the data.

# tibbles form read\_csv()

Alternatively we can read data files using the tidyverse with the read\_csv() function of the readr package from the tidyverse to make a tibble.

```
df_example_readr <- read_csv(file = "documents/data_analysis/data_file.csv")</pre>
```

You may start to notice how the tidyverse package work well together!

# Summary of tibbles and data frames

### Base R:

Using read.csv() and data.frame() you can make data frames

### Tidyverse (fancier version):

Using read\_csv() and tibble() you can make tibbles

We generally recommend using tibbles, but you are likely to run into lots of data frames with your work.

### Data frames vs tibbles

In the "tidy" data format, rownames are removed. For example, df has each car name as a row name. Here we use the head() function to see the first 2 rows of each using the n argument. In this case we would want to make the rownames a new column first before making into a tibble.

```
head(df, n = 2)
                                                                                  mpg cyl disp hp drat wt gsec vs am gear carb

## rownames\_to\_column function

If you run into losing a variable contained in your row names, you can also use rownames\_to\_column (of tibble package) to add it before turning it into a tibble to keep them:

```
# general format! not code!
{data you are creating or changing} <- # reassign if you want to keep changes
     rownames_to_column({data you are using},
                      {Name of column you are making from rownames})
head(df, n = 2)
             mpg cyl disp hp drat wt gsec vs am gear carb
             21 6 160 110 3.9 2.620 16.46 0 1
Mazda RX4
Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1
df <- rownames_to_column(df, "car")</pre>
head(df, n = 2)
           car mpg cyl disp hp drat wt qsec vs am gear carb
     Mazda RX4 21 6 160 110 3.9 2.620 16.46 0 1
2 Mazda RX4 Wag 21 6 160 110 3.9 2.875 17.02 0 1 4
```

### Let's stick with the tibble version

```
tb <- tibble(df)
tb</pre>
```

```
# A tibble: 32 × 12
                                                                                                                                        disp
                                                                                                                                                                                                   drat

# **Renaming Columns**

# Renaming Columns of a data frame or tibble

To rename columns in dplyr, you can use the rename function.

For example, let's rename mpg to MPG. Notice the new name is listed **first**!

```
# general format! not code!
{data you are creating or changing} <- rename({data you are using},
                                  \{\text{New Name}\} = \{\text{Old name}\}\}
tb <- rename(tb, MPG = mpg)</pre>
head(tb)
# A tibble: 6 \times 12
                  cyl disp hp drat wt
 car
             MPG
                                          gsec
                                                VS
                                                      am gear
 1 Mazda RX4 21
                                     2.62
                       160
                            110 3.9
                                          16.5

```

### Take Care with Column Names

When you can, avoid spaces, special punctuation, or numbers in column names, as these require quotes to refer to them.

See <a href="https://jhudatascience.org/intro\_to\_r/quotes\_vs\_backticks.html">https://jhudatascience.org/intro\_to\_r/quotes\_vs\_backticks.html</a> for more guidance.

```
tb <- rename(tb, MPG! = MPG) # this will cause an error
tb_rename <-rename(tb, `MPG!` = MPG) # this will work
head(tb_rename, 2)
# A tibble: 2 × 12
          `MPG!` cyl disp hp drat wt
 car
                                       gsec
                                             VS
                                                  am
                                                     gear
 1 Mazda RX4
             21
                      160
                          110
                             3.9 2.62
                                       16.5
                                                       4
             21
2 Mazda RX4 ...
                      160
                          110
                               3.9 2.88 17.0
                                              (-)
```

You will need to refer to a column like this with most functions.

# Take Care with Column Names and Character Strings

These are the conventions, most options will work for most functions.

Backticks are typically for nonstandard variable names:

- those with spaces col 1
- those with punctuation col.1
- those that are just numbers 1
- those that start with numbers 1st col

Single or double quotes are typically used for character strings (data values that has characters):

- "words"
- · "phrases with spaces"
- 'words'
- · 'phrases with spaces'

# Be careful about copy pasting code!

Curly quotes will not work!

```
tb_rename <-rename(tb, 'MPG!' = MPG) # this will cause an error!

tb_rename <-rename(tb, `MPG!` = MPG) # this will work!

Also true for double quotes

tb_rename <-rename(tb, "MPG!" = MPG) # this will cause an error!

tb_rename <-rename(tb, "MPG!" = MPG) # this will work!</pre>
```

# Renaming all columns of a data frame: dplyr

To rename all columns you use the rename\_with(). In this case we will use toupper() to make all letters upper case. Could also use tolower() function.

```
tb upper <- rename with(tb, toupper)
head(tb_upper, 3)
# A tibble: 3 × 12
                                                                                                                                                                                                                                                                                                                                           WT QSEC
               CAR
                                                                                                                      MPG
                                                                                                                                                              CYL DISP
                                                                                                                                                                                                                                                         HP DRAT

                                                                                                                                                                                                        108
                                                                                                                                                                                                                                                                                                                                                                                                                                     1
                                                                                                                                                                                                                                                                                                                                                                                                                                                                               1
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          4
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  1
```

# Summary

- · data frames are simpler version of a data table
- tibbles are fancier tidyverse version
- data frames are made with data.frames() and read.csv()
- tibbles are made with tibble() and read\_csv() from readr
- if your original data has rownames, you need to use rownames\_to\_column before converting to tibble
- the rename() function of dplyr can help you rename columns
- avoid using punctuation (except underscores), spaces, and numbers (to start or alone) in column names
- · if you must do a nonstandard column name, use backticks to refer to it
- quotes can be used for character values
- avoid copy and pasting code from other sources quotation marks will change!

# Lab Part 1

Class Website Lab

# **Subsetting Columns**

# Subset columns of a data frame - tidyverse way:

To grab (or "pull" out) the carb column the tidyverse way we can use the pull function:

pull(tb, carb)

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

# Subset columns of a data frame: dplyr

The select command from dplyr allows you to subset (still a tibble!)

# Select mutiple columns

We can use select to select for multiple columns.

```
select(tb, mpg, car, gear)
```

```
# A tibble: 32 \times 3
     mpg car
                            gear
   <dbl> <chr>
                           <dbl>
  21 Mazda RX4
 2 21 Mazda RX4 Wag
 3 22.8 Datsun 710
                               3 3 3 4
 4 21.4 Hornet 4 Drive
 5 18.7 Hornet Sportabout
 6 18.1 Valiant
 7 14.3 Duster 360
 8 24.4 Merc 240D
 9 22.8 Merc 230
10 19.2 Merc 280
# ... with 22 more rows
```

# Subset columns of a data frame: dplyr

Note that if you want the values (not a tibble), use pull - as it pulls out the data:

```
pull(tb, mpg)

[1] 21.0 21.0 22.8 21.4 18.7 18.1 14.3 24.4 22.8 19.2 17.8 16.4 17.3 15.2 10.5 16] 10.4 14.7 32.4 30.4 33.9 21.5 15.5 15.2 13.3 19.2 27.3 26.0 30.4 15.8 19.5 15.0 21.4

# pull with select works too!

pull(select(tb, mpg))

# Select columns of a data frame: dplyr

The select command from dplyr allows you to subset columns matching patterns:

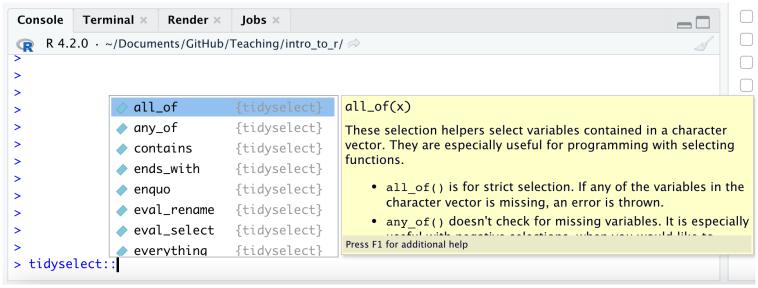

```
head(tb, 2)
# A tibble: 2 \times 12
                   cyl disp hp drat wt
 car
              mpg
                                           qsec
                                                 VS
                                                      am

## See the Select "helpers"

Here are a few:

```
last_col()
starts_with()
ends_with()
contains() # like searching
```

Type tidyselect:: in the console and see what RStudio suggests:

## Combining tidyselect helpers with regular selection

```
head(tb, 2)

# A tibble: 2 × 12
car mpg cyl disp hp drat wt qsec vs am gear ca
<chr> <dbl> <dbl>
```

## Multiple tidyselect functions

Follows OR logic.

```
tb %>%select(starts_with("c"), ends_with("r"))
# A tibble: 32 \times 4
                        cyl carb gear

                                                            21.4
                                                                                                                                                                                                     18.6
```

You can have multiple logical conditions using the following:

- · ==: equals to
- !=: not equal to (! : not/negation)
- · > / <: greater than / less than
- >= or <=: greater than or equal to / less than or equal to</li>
- · &: AND
- · |: OR

#### Common error for filter

If you try to filter for a column that does not exist it will not work:

- misspelled column name
- column that was already removed

11 Volvo 142E

21.4

4 121

You can filter by two conditions using & or commas (must meet both conditions):

```
filter(tb, mpg > 20, cyl == 4) # same result
filter(tb, mpg > 20 \& cyl == 4)
# A tibble: 11 × 12
                                                                                 cyl disp
                                                                                                                              hp drat

If you want OR statements (meaning the data can meet either condition does not need to meet both), you need to use | between conditions:

```
filter(tb, mpg > 20 | cyl == 4)
# A tibble: 14 × 12
                    cyl disp
                                hp
                                   drat
  car

                                                                                                                                                                                                                                                                                                                                                                                                                                        6
                                                                                                                                     6 145
                                                                                                                                                                                                                                                                                                                                       0
```

## distinct() function

To filter for distinct values from a variable, multiple variables, or an entire tibble you can use the distinct() function from the dplyr package.

```
distinct(tb, cyl)
# A tibble: 3 \times 1
    cyl
  <db1>
distinct(tb, cyl, gear)
# A tibble: 8 × 2
    cyl gear
  <db1> <db1>
2
3
4
              3 3 5 5 5
5
       4
6
```

#### Summary

- pull() to get values out of a data frame/tibble
- select() is the tidyverse way to get a tibble with only certain columns
- you can select() based on patterns in the column names
- you can also select() based on column class with the where() function
- you can combine multiple tidyselect functions together like select(starts\_with("C"), ends\_with("state"))
- you can combine multiple patterns with the c() function like select(starts\_with(c("A", "C")))
- filter() can be used to filter out rows based on logical conditions
- == is the same as equivalent to
- & means both conditions must be met to remain after filter()
- | means either conditions needs to be met to remain after filter()
- distinct() helps you filter for unique values

# Lab Part 2

Class Website Lab

# Combining filter and select

You can combine filter and select to subset the rows and columns, respectively, of a data frame:

```
select(filter(tb, mpg > 20), cyl)
# A tibble: 14 \times 1
      cyl
   <db1>
 123456789
10
11
12
13
14
```

# Nesting

In R, the common way to perform multiple operations is to wrap functions around each other in a "nested" form.

```
head(select(tb, car, cyl), 2)
```

# Nesting can get confusing looking

```
select(filter(tb, mpg > 20 \& cyl == 4), cyl, hp)
# A tibble: 11 \times 2
     cyl
            hp
   <db1> <db1>
            93
 123456789
       4
         62
         95
           66
            52
           65
            97
       4
         66
       4 91
10
       4
           113
11
       4
           109
```

# **Assigning Temporary Objects**

One can also create temporary objects and reassign them:

#### Using the pipe (comes with dplyr):

The pipe %>% makes this much more readable. It reads left side "pipes" into right side. RStudio CMD/Ctrl + Shift + M shortcut. Pipe tb into filter, then pipe that into select:

```
tb %>% filter(mpg > 20 & cyl == 4) %>% select(cyl, hp)
```

```
# A tibble: 11 \times 2
      cyl
               hp
    <db1> <db1>
                93

```

# Adding/Removing Columns

# Adding columns to a data frame: dplyr (tidyverse way)

The mutate function in dplyr allows you to add or modify columns of a data frame.

```
# General format - Not the code!
 {data object to update} <- mutate({data to use},
                                                                                                                            {new variable name} = {new variable source})
tb <- mutate(tb, newcol = wt / 2.2)
head(tb, 4)
# A tibble: 4 × 13
         car
                                              mpg
                                                                       cyl disp
                                                                                                                                   hp drat
                                                                                                                                                                                         wt qsec
                                                                                                                                                                                                                                                 VS
                                                                                                                                                                                                                                                                             am gear carb newcol

## Removing columns of a data frame: dplyr

The **NULL** method is still very common.

The select function can remove a column with minus (-):

```
select(tb, - newcol)
# A tibble: 6 \times 12
                 cyl disp
                           hp
                              drat
                                     wt
 car
                                        qsec
                                              VS
                                                      gear
             mpq
                                                   am

```

Or, you can simply select the columns you want to keep, ignoring the ones you want to remove.

## Removing columns in a data frame: dplyr

You can use c() to list the columns to remove.

Remove newcol and drat:

```
select(tb, -c("newcol", "drat"))
# A tibble: 32 × 11
                          cyl disp
  car
                     mpg
                                      hp
                                           wt
                                               gsec
                                                      VS
                                                                gear
                                                            am

1.

1.

The select function can reorder columns. Put newcol first, then select the rest of columns:

```
select(tb, newcol, everything())
# A tibble: 3 \times 13
              newcol car
                                                                                                                                                            cyl disp
                                                                                                                                                                                                                                                      hp drat
                                                                                                                    mpg

                                                                                                                                                                                                                                                                                   1
# ... with 22 more rows, and 1 more variable: wt <dbl>
```

In addition to select we can also use the relocate() function of dplyr to rearrange the columns for more complicated moves.

For example, let say we just wanted wt to be before cyl.

```
head(tb, 1)
 # A tibble: 1 × 13

                                                                                                                                                                                                                                                                  (-)
# ... with 22 more rows, and 1 more variable: newcol <dbl>
```

## Summary

- select() and filter() can be combined together
- you can do sequential steps in a few ways:
  - 1. nesting them inside one another using parentheses ()
  - 2. creating intermediate data objects in between
  - 3. using pipes %>% (like "then" statements)
- select() and relocate() can be used to reorder columns
- arrange() can be used to reorder rows
- can remove rows with filter()
- can remove a column in a few ways:
  - 1. using select() with negative sign in front of column name(s)
  - 2. not selecting it (without negative sign)

## Summary cont...

mutate() can be used to create new variables or modify them

#### A note about base R:

The \$ operator is similar to pull(). This is the base R way to do this:

tb\$carb

Although it is easier (for this one task), mixing and matching the \$ operator with tidyverse functions usually doesn't work. Therefore, we want to let you know about it in case you see it, but we suggest that you try working with the tidyverse way.

## Adding new columns to a data frame: base R

You can add a new column (or modify an existing one) using the \$ operator instead of mutate.

Just want you to be aware of this as it is very common.

tb\$newcol <- tb\$wt/2.2

```
head(tb,3)

# A tibble: 3 × 13
car mpg cyl disp hp drat wt gsec vs am gear carb newo
```

```

                                                                                                                                                                                                                                                                                                                            93
                                                                                                                                                                                                                                                                                                                                                                       3.85
                                                                                                                                                                                                                                                                                                                                                                                                                                        2.32
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         18.6
```

Even though \$ is easier for creating new columns, mutate is really powerful, so it's worth getting used to.

## which() function

TRUE

FAI SF

[17,] [18]

Instead of removing rows like filter, which() simply shows where the values occur if they pass a specific condition. We will see that this can be helpful later when we want to select and filter in more complicated ways.

```
which(select(tb,carb) == 4)
 [1]
      1 2 7 10 11 15 16 17 24 29
select(tb, carb) == 4
       carb
       TRUE
       TRUE
      FALSE
      FALSE
      FALSE
      FALSE
       TRUE
      FALSE
      FALSE
10, ]
      TRUE
[11,]
      TRUE
      FALSE
13,]
      FALSE
14,]
      FALSE
[15,]
       TRUE
16,]
       TRUE
```

# base R subsetting

## Subset columns of a data frame:

We can grab the carb column using the \$ operator. This is the base R way to do this:

#### df\$carb

[1] 4 4 1 1 2 1 4 2 2 4 4 3 3 3 4 4 4 1 2 1 1 2 2 4 2 1 2 2 4 6 8 2

## Remove a column in base R

df\$mpg <- NULL

## Renaming Columns of a data frame: base R

We can use the **colnames** function to extract and/or directly reassign column names of **df**:

```
colnames(df) # just prints
 [1] "car" "mpg" "cyl" "disp" "hp" "drat" "wt" "qsec" "vs"
                                                                      "am"
[11] "gear" "carb"
colnames(df)[1:3] <- c("MPG", "CYL", "DISP") # reassigns</pre>
head(df)
                MPG CYL DISP disp hp drat wt qsec vs am gear carb
          Mazda RX4 21.0
                               160 110 3.90 2.620 16.46
     Mazda RX4 Wag 21.0
Datsun 710 22.8
Hornet 4 Drive 21.4
                               160 110 3.90 2.875 17.02
                                    93 3.85 2.320 18.61
                               108
                                                                        12
     Hornet 4 Drive 21.4
                            6
                               258 110 3.08 3.215 19.44
5 Hornet Sportabout 18.7 8 360 175 3.15 3.440 17.02
            Valiant 18.1
                            6 225 105 2.76 3.460 20.22 1
colnames(df)[1:3] <- c("mpg", "cyl", "disp") #reset - just to keep consistent</pre>
```

## Renaming Columns of a data frame: base R

We can assign the column names, change the ones we want, and then re-assign the column names:

#### Subset rows of a data frame with indices:

Let's select **rows** 1 and 3 from **df** using brackets:

```
df[c(1, 3),]
```

```
mpg cyl disp disp hp drat wt qsec vs am gear carb
1 Mazda RX4 21.0 6 160 110 3.90 2.62 16.46 0 1 4 4
3 Datsun 710 22.8 4 108 93 3.85 2.32 18.61 1 1 4 1
```

### Subset columns of a data frame:

We can also subset a data frame using the bracket [, ] subsetting.

For data frames and matrices (2-dimensional objects), the brackets are [rows, columns] subsetting. We can grab the x column using the index of the column or the column name ("carb")

#### Another difference between **tbl** and data frame:

3 22.8 4 21.4

5 18.7 6 18 1

Mostly, tbl (tibbles) are the same as data frames, except they don't print all lines. When subsetting only one column using brackets, a data frame will return the values, but a tbl will return a tbl

```
df[, 1]
     "Mazda RX4"
                            "Mazda RX4 Wag"
                                                    "Datsun 710"
                                                    "Valiant"
     "Hornet 4 Drive"
                            "Hornet Sportabout"
     "Duster 360"
                            "Merc 240D"
                                                    "Merc 230"
10] "Merc 280"
                            "Merc 280C"
                                                    "Merc 450SE"
13] "Merc 450SL"
                            "Merc 450SLC"
                                                    "Cadillac Fleetwood"
                                                    "Fiat 128"
 [16] "Lincoln Continental" "Chrysler Imperial"
                            "Toyota Corolla"
 [19] "Honda Civic"
                                                    "Toyota Corona"
                                                    "Camaro Z28"
 [22] "Dodge Challenger"
                            "AMC Javelin"
 [25] "Pontiac Firebird"
                            "Fiat X1-9"
                                                    "Porsche 914-2"
[28] "Lotus Europa"
                            "Ford Pantera L"
                                                    "Ferrari Dino"
[31]
     "Maserati Bora"
                            "Volvo 142E"
tbl[, 1]
# A tibble: 32 \times 1
     mpg
   <db1>
    21
   21
```

#### Subset columns of a data frame:

We can select multiple columns using multiple column names:

```
df[, c("mpg", "cyl")]
```

```
mpg
                         CAT
              Mazda RX4 21.0
123456789
         Mazda RX4 Wag 21.0
             Datsun 710 22.8
        Hornet 4 Drive 21.4
     Hornet Sportabout 18.7
                Valiant 18.1
             Duster 360 14.3
              Merc 240D 24.4
               Merc 230 22.8
10
              Merc 280 19.2
11
              Merc 280C 17.8
12
             Merc 450SE 16.4
13
             Merc 450SL 17.3
14
           Merc 450SLC 15.2
15
    Cadillac Fleetwood 10.4
16 Lincoln Continental 10.4
17
     Chrysler Imperial 14.7
18
               Fiat 128 32.4
19
            Honda Civic 30.4
20
        Toyota Corolla 33.9
21
         Toyota Corona 21.5
22
      Dodge Challenger 15.5
23
           AMC Javelin 15.2
24
             Camaro Z28 13.3
25
      Pontiac Firebird 19.2
```
